COPYING RESTRICTIONS

Reel duplication of the whole or of any part of this film is prohibited. In lieu of transcripts, however, enlarged photocopies of selected items contained on these reels may be made in order to facilitate research.

A Note on the Sources

The pages which were microfilmed for this collection are in generally good condition in the original. There are some pages, however, which due to age are lighter than normal. Additionally, because some volumes are very large and have been bound tightly and cannot be unbound, there are intermittent occurrences of slight distortion of the edges of a small percentage of the pages. We have made every technical effort to ensure complete legibility of each and every page.

THE REDUCTION RATIO FOR THIS REEL IS 16:1

IMPROVED INSULATOR AND PROTECTOR FOR UNDERGROUND LINES.

The great problem in telegraphy and telephony seems to be the disposition of the wires. Looking up from many of our New York streets, one can but wonder that the multitude of wires extending in every direction perform their function with so little interference one with another. Still

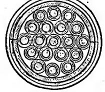
1.

FRENCH'S INSULATOR AND PROTECTOR FOR UNDERGROUND LINES.

the trouble caused by "crosses," breakages during storms, and by the excursions of line men in building and repairing lines, is very great, and daily increasing, and a remedy is demanded. Clearly some system of underground lines is preferable to any arrangement of overhead wires. We give an engraving of one of the latest, and apparently a very practicable device for insulating and protecting underground telegraph and telephone wires, the invention of Mr. William A. French, of Camden, N. J.

The protector or outer casing consists of a tube of hard rubber made in ten-foot lengths and of a diameter suited to the number of wires to be used. The ends of the tubes are united by a water-tight joint. Short connecting tubes, made

2



SECTION OF INSULATOR AND PROTECTOR.

in halves, join the longer lengths and admit of being removed to insert or remove the conductor.

The lengths of large tubing are filled up with smaller tubes of soft rubber, which project a short distance from the ends of the large tube into the connecting tubes, where they meet the ends of the corresponding tubes of the adjacent section, and are connected by a short coupling of hard rubber.

The small tubes are of such size as to admit of readily inserting and removing the telegraph wire. In some cases the inventor covers the wire with a protective coat of insulating material before placing it in the small tubes.

In applying the invention to practical use the telegraph wires are passed through the small soft rubber tubes of a number of hard rubber tubes, which are placed at such a distance apart that the ends of the soft rubber tubes will meet. The ends of the corresponding tubes are then connected by the small hard rubber couplings. The divided connecting tubes are then applied to the adjacent ends of the hard rubber tubes, and the coupling bands are screwed on the collar, the joints being made tight by cement or packing.

The soft rubber tubes can be made of any desired length, and can be inserted in the hard rubber tubes before or after the hard rubber tubes have been put in position, and the half section tubes can be dispensed with, in whole or in part.

6

Electrician Feb 14 1880

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).

The ordinary general half-yearly meeting of the above Company was held at the City Terminus Hotel on the 6th inst., under the presidency of Viscount Monck, the chairman.

The SECRETARY (Mr. John Grant) read the advertisement convening the meeting, and the minutes of the last ordinary general meeting, which were confirmed by the present meeting, and signed as correct by the chairman.

The report of the directors, the salient features of which appeared in *The Electrician* of last week, was taken as read.

The CHAIRMAN, in moving the adoption of the report and accounts, and the payment of the dividend in accordance therewith, said: The natural division of the subjects which he had to bring before them coincided with that which prevailed in a larger and more important annual meeting in which he took some concern on the previous day—namely, to divide itself into their domestic and foreign relations. With regard to their home work, the report, he thought, had made it pretty plain that he had nothing to tell them that was not eminently satisfactory. Their property was in good condition, and their cables were working with their usual efficiency; while their income had, as they would observe, very largely increased within the last half year as compared either with the preceding half year or the corresponding six months of 1878. They proposed, as they stated at the last half-yearly meeting, to lay down a new cable this year between Ireland and America, and they had the pleasure to tell the proprietors that they were in a position to do that without asking them or the public for one shilling of the money. They proposed in addition to that to lay down or renew, as they would observe by the report, other portions of their system, which had either worn out or become inefficient—he referred to the short cables connecting the Island of Newfoundland with the continental portion of America, and that was a work which was absolutely necessary to be done in order to the efficiency of their system. They proposed to do that also out of money in hand. There was some doubt expressed at their last meeting, he thought, about the propriety of laying down a new cable between Ireland and America this year. The argument used, as he recollected it, was that when a cable got to the bottom of the sea it more or less deteriorated in quality, and, therefore, the longer, consistently with the efficient performance of their work, they could put off laying down a new cable the better. Well, no one was more ready than he to admit the general soundness of that argument; but it must be taken with certain qualifications. In the first instance, the enormous increase in their traffic had rendered it absolutely necessary that they should keep at least three cables in full work. Their three cables were working, each performing its full share of the work; but they must remember that one of those cables was very nearly eleven years old, and, without any disparagement to its condition, they must be prepared for contingencies—he would go no further than that. There was another view of the matter. He had not yet alluded—and his allusion would be very short—to their foreign relations, and by that he meant to express what they were all aware of, the cable which had been laid down by the new French company. The result of that would be a competition, and competition, as he understood, and as they had already announced, could only be carried on by a very considerable reduction of tariff, and a very considerable reduction of tariff meant nothing more than a very considerble increase of traffic; and in order to carry that increase of traffic with a reduced tariff as efficiently as they had done hitherto, they must be prepared with additional instruments for the working of that traffic. There was another view of the matter. They were not fools: they did not mean to go on competing and fighting for ever. Sooner or later they must come to an arrangement, and their share of profit arising out of that arrangement would depend very materially on the number of efficient cables they would have when it was made. He thought he need not trouble them further on that point, because he was satisfied, from the tokens of assent from all parts of the room, that the proprietors were convinced that the Board ought at once to exercise the powers they had of laying down the new cable. They had made arrangements, or arrangements were in progress, for a new survey of the bed of the Atlantic, so as to obtain, if possible, a better resting place for their new cable than had been afforded to those which had preceded it. It had been suggested that they should make experiments as to the coating of their cables. Well, that was a matter on which they had been engaged, and they were in great hopes, from the turn things had taken, and the result of the experiments made, that they would be able to get a class of cable which would more effectually resist the deterioration of whatever influences might be brought to bear on it under the water than any yet which had been laid down. He might say at once with respect to this new cable that they were doing everything they could to secure an intrinsic superiority in the cable itself, and the best possible bed for it in the bottom of the Atlantic. He did not know that there was anything else connected with their home relations to which he need refer, but he might anticipate some objections which might be made with respect to the expenditure of the last half year. They would see by abstract A—expenses at the head office in London—that there was a considerable reduction, a reduction of £850 odd in expenses at the head office during the last year. There was a considerable increase in the expenses at the out stations, but he thought if any gentleman would take the trouble of running his eye down that column and see the points in which the principal increase had taken place, he would at once recognise that it was attributable to the enormously increased traffic, and that it was only a very small percentage they paid for their increased gains. They could not do double the work without getting double assistance for it; and if they had double assistance they must pay for it. That was really the whole explanation. There were certain large items. For instance, there was the item of maintenance of land lines, instruments, and instrument stores, which they could not avoid—things would wear out and they must replace them. Then, repairs and furniture—that came under the same denomination. They had also been obliged to put up additional buildings at Valentia for their increased staff there, and in order to replace the building worn out. There was also an increase in the expenses for use of patents. They had duplexed all their Irish and Newfoundland cables, which were working most admirably, but for which they must pay. So far for their home work. He had alluded, incidentally, to the French company. The French company had laid down their cable to America, and they had been expecting that the competition would begin, but up to that time the French company had not interfered with them in the slightest degree, though they had announced that they were open. They were told a year or a year and a half ago, when that operation was first started, that one of the first motives of those patriotic individuals who set it to work was to gratify the *amour propre* of the French people, and it appeared that that was not only incidentally their object, for it appeared to be their only object. It appeared that they were quite satisfied to have laid the cable without working it. How long that was to continue they did not know, but he did not care how long it lasted, having regard to the proprietors' interests, for every day the French company acted on that principle of self-abnegation was worth thousands to this Company. At the same time, if they offered this Company terms which they considered reasonable, they were not averse to work at amity with them. His belief was that there was room for them all. With those observations he would ask them to place the same confidence in their directors which the latter had so often experienced at their hands, and to leave the negotiations with them to deal with as they thought best. He considered that the state of their affairs proved that the directors were entitled to their confidence. He thought that the gloomy anticipations which for several years past had been made with regard to the future of the Company had not—at all events up to the present—been realised; and his thorough conviction was that as they had gone on for the last ten years, so they would go on in the future, managing their affairs with prudence and determination, realising for them a fair revenue on their outlay, and maintaining their property in good and serviceable condition.

Sir DANIEL GOOCH, Bart., M.P., one of the directors, seconded the motion.

Mr. GREENWOOD wished to ask a question, but not to oppose the motion in any way. He observed, however, in the report the following paragraph:—"The directors, under the powers conferred upon them by the articles of association, have, before declaring the net profits, set apart the sum of £146,000 to the renewal fund." That was a very enormous amount, representing, if set aside every half year, £280,000 a year. He was not, however, finding fault with the amount. He thought in present circumstances that it was most judicious to set aside a large amount; but he wished to know what were the exact powers of the directors in the matter. What was the limit? Or could the directors go on putting such an amount aside for as long as they thought proper?

Mr. JACKSON wished to ask a question as to the paragraph in the report which referred to the abandonment of two of the cables. He desired to know the cost of replacing them, as he thought it would be satisfactory to the shareholders to know. He thought, with regard to the report itself, that the impression on the shareholders must be twofold; first, that of serious depression that two more cables—though, it was true, they were not deep-sea cables—were actually abandoned by the Company. That, however, was a perfect evidence of the judiciousness and the necessity of the directors in providing such a large reserve fund for these matters, but he thought the fact of such abandonment was a subject for regret. A matter of unmixed satisfaction was that their receipts for 1879 had exceeded those of 1878 by £116,000, though they were not permitted to divide it. There was one satisfactory feature in connection with what the chairman had said as to the French company and dividing the profits on the basis of the number of cables on the ground. It should, however, be remembered that the new company, with its new cable, had to work its way, as this Company had done, through trials and difficulties, before it realised a moderate result; but even supposing, in any arrangement being come to, it did get its proportion of the profits, it would receive only one-sixth, which would come within the amount of the increased profit this Company had made in the past year. He mentioned that because he thought it might be satisfactory to those shareholders who might not have gone into the figures to know that even if they were deprived of one-sixth they would still have what would give them their present dividend, which he thought was very satisfactory, particularly to those who had bought their shares at present prices. He was very gratified to hear the chairman's remarks as to the experiments which had been made for securing an improved outer covering for their cables, and to believe, as he gathered from those remarks, that they had accomplished satisfactory results as to sheathing the cable with such a substance as would make it more durable. If they could see a fair chance of looking to fifteen or twenty years as the "life" of a cable, a quarter, or half, at the most, of their present reserves would suffice for the purpose. He knew that their manager liked to be "square," and give the shareholders plain facts and the plain truth, but he hoped that gentleman might be able to confirm the aspirations which he (the speaker) had expressed.

Mr. SEELEY asked the reason of the Board for abandoning the daily publication of the returns of the traffic. He was very much surprised to hear that the French company had not commenced to work. He thought that they had; and that they were in competition. He also asked a question with regard to the item in the renewal fund of "cash not yet invested," £115,000, and the item on the credit side of the balance-sheet of deposit and ordinary cash balances, £46,000.

Mr. J. NEWTON said he was surprised and disappointed to hear the chairman say that they had entered into negotiations with the new French company. From the number of meetings he had attended of this Company, he thought they had determined to fight for the monopolies which were granted to this Company when it first started—monopolies which he believed no company that was ever formed in the world more righteously deserved. This Company, at its own expense, proved to the world that it was possible to lay a submarine cable in deep water. For that great work they obtained the monopoly and privilege of having the traffic throughout all England, most of the traffic of North Germany, the traffic of all France, and practically, the command of the traffic for the whole of Europe, for the great work the Company had done. He thought that, with the strong position they occupied, negotiations should not have been entered into with the new French company so early. It appeared that they had been over here, and had had negotiations with the Board, and the result had been known, or presumed to be known, on the Stock Exchange, and the shares had been going up and down as a consequence.

The CHAIRMAN: Up, not down.

Mr. NEWTON thought, seeing that this cable was not required, that it was not a cable called into existence by money provided by shareholders, but the result of the jobbing work of a set of cable manufacturers, who were the enemies of all those who had invested money in these companies, that what the chairman had said was matter for surprise. There had been something like £20,000,000 laid out for the purpose of providing the world and civilisation with this great work, and because it had been done so well, and it was just possible that some other company might like to get some of the plums of the work, those jobbers made cables before they were wanted, and then came to companies like this and wished to negotiate. He was perfectly surprised to hear that a compromise would be based on the number of effective cables they possessed. He remembered the competition threatened on a former occasion; but after the amalgamation of this Company with the French Atlantic Company, and in view of it he sent a proposition to the directors, indirectly suggesting that instead of the scheme of preferred and deferred stocks they should, under the amalgamation, adopt the system of preferred and deferred messages, the Anglo carrying the deferred, and the original French Atlantic Company the preferred messages, the former to be carried at rates which would command nearly all the traffic from Europe to America, and the preferred messages, the most important ones, to be charged a higher tariff. He believed it was said at the time that that could not be done legally, owing to the amalgamation; but it might be done now, the Anglo taking the deferred and the Direct the preferred messages. He thought, with the strong position now occupied by the Anglo Company, that by going down to sixpence or threepence a word they could take every message sent from Europe to America, unless specially directed to go by the new competing French company. This Company must have the messages—there was no power to prevent it if they had the same rates as the French company. They would then be able to dictate terms to the new competing jobbing cable. With this Company's monopolies they could put that company in such a position that their receipts would bring them to an arrangement on a much lower level than on the basis of having one cable against five; they were, therefore, entitled to one-sixth of the total receipts. He maintained that if they would fight the French company for a little longer they would buy them up on the same terms as they did, practically, on a former occasion, when they took over another jobbing company. He thought the Board appeared somewhat as if they had been caving in.

The CHAIRMAN said he would try and answer as well as he could the several questions put to him. Mr. Greenwood had asked what were the powers of the directors to add to the renewal fund. The powers were unlimited by the articles of association, but he might at once explain that they had no intention of maintaining the contribution to the renewal fund to the same extent as they had done this half year. It was a purely exceptional case. They had had very large receipts, and they would have very large outgoings this next year, and they had laid aside this extraordinary sum, about £65,000 more than they had laid otherwise, to enable them, as was stated before, to do all the permanent work they would be called on to do this year without calling on the proprietors for any further capital. Mr. Jackson had asked a question as to the island cables. Those were very old cables; they were not laid by this Company, but by the Newfoundland company, and Mr. Jackson, who was perfectly conversant with all the changes that had taken place, would recognise how old they must be. They were ten or twelve years old, and they must be renewed.

Mr. JACKSON said he had asked as to their cost.

The CHAIRMAN: The expense would, probably, be about £100,000. As to the publication of the returns of their traffic, they were, more or less at that moment, in a state of war with the French company, and the abandonment of the publication of their daily returns was somewhat equivalent to what was known on the Continent as a declaration of a state of siege. They did not want, while they were contesting or fighting with that company, to let them see their hands, and to show them what effect the diminution of traffic had on their income, and that was why they kept this information to themselves. He might tell them, as a matter of fact, that the traffic for January amounted to a very tidy sum, and he could assure them that they need not be the least alarmed. There was another question asked with regard to the balance at their banker's at the close of the year. The fact was that that balance consisted of bills not already due, and items of that description, which had probably all been received and paid away since. They must remember that it was then six weeks since the end of the year, and they were obliged to make their balances with their bankers; they debited their bankers with all bills lodged for collection and not yet matured. With regard to the bellicose observations of the gentleman who sat opposite (referring to Mr. Newton), he thought that before he sat down he would satisfy the meeting that that gentleman had not the slightest foundation for the oration he had made on that occasion. Mr. Newton, in the first place, said they ought to fight for their monopolies. Well, he was a free trader, and as such was opposed to monopolies, but, on the other hand, if they had a monopoly which was advantageous to this Company he should be very much inclined to put his free trade principles into his breeches pocket; but, unfortunately, they had never had a monopoly. The only thing they had approaching to a monopoly was that they had an undertaking from the British Post Office, and a concession from the French Government, giving to the Company any messages which might be sent through their wires not directed to go by another cable. And so with North Germany. That monopoly was not interfered with in the least degree, if it were a monopoly. Well, that took away, as it appeared to him, the main foundation for the speech they had heard from Mr. Newton. But that gentleman went on to say that they had a partner, the Direct company, and three cables of their own, and asked why they did not make use of the advantages which that state of things gave them—why did they not carry at very low rates, and let their partner carry special messages at a higher rate? Perhaps it would surprise that gentleman very much to know that that was precisely the arrangement they had made. Therefore, all that magnificent eloquence in favour of defending their rights [expressions of dissent, and interruption]—he was speaking in the most good-humoured disposition, but Mr. Newton had made a speech in favour of what they had done, and what he meant was that they had done precisely what Mr. Newton had suggested should be done. He must say that the speech was made in a rather criticising manner; and when it amounted to saying that they ought to do what they had done he thought he had disposed of the speech. Mr. Newton further said that they ought to fight and not to cave in. He begged to say that as far as any utility could be got from fighting, he was as ready to fight as any man, but the caving in was not of their seeking. The other company came to them and offered them certain terms, and asked them if they would accept them. As he said at the beginning of the meeting, those negotiations were still in progress, and, as he heard a very distinguished statesman say on the previous night, nothing could be more mischievous to the result of negotiations than questions put when they were in progress. He must, therefore, adopt the same observation, but as to saying that they had caved in, he assured Mr. Newton and the meeting that if it were possible, without prejudice to the interest of the Company, to put them in possession of all that had taken place, they would find, so far from caving in, they were as stiff as they could be. He assured them that they would look after the interests of the proprietors in this competition, and act to the best of their ability. They had had some dark periods in their history before, and without arrogating any undue credit to themselves, he thought they had pulled them through pretty well. He, therefore, hoped that without further reference to competition and fighting, they would adopt the resolution, and leave the conduct of this matter in the hands of the directors.

Mr. NEWTON desired to remind the chairman that he had not asked a single question. He had the utmost confidence in them, knowing that they would preserve the rights of the proprietors. He had it, however, on the official paper of the Company, that the monopolies to which he had referred were monopolies. He had that among his private papers, and under the signature of one of the gentlemen sitting at the Board.

The CHAIRMAN then put the motion, which was carried unanimously.

He next moved the re-election as a director of Mr. Francis A. Bevan.

Sir JAMES ANDERSON seconded the motion, which was carried unanimously.

On the motion of the CHAIRMAN, seconded by the Hon. ROBERT GRIMSTON, the other retiring director, Mr. L. M. Rate, was also re-elected.

Mr. JACKSON then moved the re-election of the retiring auditors, Mr. Joshua Dear and Mr. Francis Glass. He expressed his pleasure at submitting the resolution, and hoped the auditors would make any suggestion they properly could which would give the shareholders a slight increase to their dividend.

Mr. SEELEY seconded the motion, and it was carried unanimously.

Mr. NEWTON then moved a vote of thanks to the chairman and directors. They knew how they were treated at some of the meetings of these companies, and he believed they would all agree with him that Viscount Monck bore off the palm among chairmen, for even when his lordship had anything unpleasant to say he said it in such a manner as to leave no feeling of irritation behind.

Mr. SEELEY seconded the motion, which was carried unanimously.

The CHAIRMAN, in acknowledging the vote, returned his sincere thanks to the meeting for the confidence they had reposed in their Board, and to Mr. Newton for the expression of his opinion of his (the chairman's) urbanity. He felt very much indebted to them, but he would ask them to include in the resolution the officers of the Company.

Mr. NEWTON requested that he might be allowed to include the officers, and threw out the suggestion whether some pecuniary recognition of their services could not be made, observing that it would go to pay the income tax of those gentlemen. He had spoken on some occasions in favour of economy, but he did not think economy should be exercised towards those who worked for them.

The CHAIRMAN again thanked the meeting, and the proceedings then terminated.

Tel Jour. Feb. 1. 1877

The laying of cables betweeen Halle-Leipzic, Halle-Cassel-Frankfort-Mayence, Berlin-Hamburg and Hamburg-Kiel, is to be commenced, we learn from the *Magdeburg Zeitung*, as soon as the ground is free of frost. The firms of Siemens and Halske, in Berlin, and Felten and Guillaume, in Cologne, are engaged in preparation of the cables. The laying will proceed much more easily than in the case of the Halle-Berlin cable. Dr. Siemens has devised a machine which makes the trench, and deposits the cable, and it is only necessary that a gang of workmen follow to fill in the trench. Siemens' machine will be used on those stretches of road where the making of the trench is not hindered by undergroud rock; in the latter case dynamite blasts are necessary. The cables are to lie one metre deep; the bottom of the trench must be of equal depth throughout, that the cable may be secure, and this is effected by the machine. The laying will be easiest between Berlin, Hamburg, and Kiel, the ground being here uniformly sandy and clayey. The Cassel-Mayence stretch will require much more labour and be more costly. The cost, however, has been carefully estimated. As the work of laying is to begin at several points at the same time, the work may be completed by the beginning of the hot season; it is anticipated, at least, that all the cables will be at work by September. The Halle-Berlin coble is giviog every satisfaction, and the experience with it has materially conduced to an extension of the system.

Trial of Direct Communication between London and Malta, with Brown and Allan's Relay. By M. GRAMMACCINI.

This experimeot was made at Marseilles. The relay oamed is a Siemeos' relay improved by addition of a contact-rod, giving moch more rapid action. One translation, worked by hand, was arranged at Bona, onother at Marseilles; there were besides, the ordinary translations of Paris and Beachey Head. The average of transmission did not exceed nine or ten words per minute; and the transmission was generally defective, the *employés* not beiog used to this kind of work; hence loss of time in rectification. Thus direct translation through a long land-line connected with a long submarine cable is shown to be possible; but the author doubts if it has real practical interest. There would be economy in *employés* and a single translation; but, on the other hand, the work is first less ropid, and the tronslation must be suspended from time to time to permit the sending of locol telegrams. Supposing no local traffic, the trausmission would still be disadvantageous, for the cable is a capital which should produce as many telegrams hourly. It is thus important to have the maximum production, and this is at present obtoined by use of the Thomson mirror apparotus or the recorder. With the Morse, the cable without translation can hardly give more than 20 telegrams an hour, or 480 in twenty-four hours; with translation, it will give only 15 or 380; but the land-line is generally interrupted four or five hours in the twenty-four, which reduces the work produced to about 300 telegrams, while the land-line alone could produce an average of 25 telegrams hourly, or 600 in twenty-four hours, that is, even failing the lost hours for working the coble.

UNDERGROUND TELEGRAPH LINES IN GERMANY.

By EDOUARD RAU.

ON the 23rd of July last there was submerged in the Rhine, near Mayence, the cable completing the one of the two great subterranean lines—that of Berlin-Mayence (Metz)—to establish which the German Parliament voted a sum last year.

Germany is, then, the first power which, after long hesitation it is true, established subterranean lines on a large scale.

The amalgamation of the postal and the telegraph administrations has powerfully contributed to accelerate this important reform. The unsuccessful attempts which took place some eleven years ago under the special direction of M. Chauvin, the then director of telegraphs for the Prussian Government at Cologne, had greatly tended to confirm the doubt of the practicability of underground telegraphs. Later on financial difficulties prevented further experiments. This difficulty now ceases to exist, in consequence of the unioo of the postal and telegraph services, a union which allowed of the reduction from 2,000 to 50 of the number of independent telegraph offices, and which, in consequence, reduced considerably the working expenses.

The excessive increase and continuation of the number of faults which occurred on the aerial wires led to the reopening of the question of underground wires. The following official returns will give an idea of the number of faults which have occurred. In 1874 there were 350 poles broken, 875 breaks in the wires, 2,826 interruptions from contact or earth. In 1875 there were 506 poles broken, 1,405 breaks in the wires, 4,076 interruptions from earth or contact. In 1876 the numbers were: breaks in poles, 1,708; breaks in the wires, 3,284; and 4,415 faults from earth or contact.

This increase in the number of occidents was out of all proportion to the number of lines. In 1874 the length of line in use was 31,035 kilometres, representing a mileage of wire equal to 107,645 kilometres. In 1875 there was 34,141 kilometres of line and 123,455 kilometres of wire; and in 1876, 37,264 kilometres of line and 138,891 kilometres of wire.

There were, then, in 1874, for 10 kilometres, 0·11 pole-breaks, 0·08 wire-breaks, and 0·26 earths or contacts; in 1875, 0·15 pole-breaks, 0·12 wire-breaks, and 0·33 earths or contacts; and in 1876, 0·46 pole-breaks, 0·24 wire-breaks, and 0·32 earths or contacts.

All, except during the year 1876, during which the telegraph system had suffered from a hurricane on March 12 and 13, and from storms on November 12 and 13, showed from 1874 to 1875 an increase of faults in the proportion of one to two, whilst the increase in the mileage of line was only in the proportion of 10 to 11, and the increase in the mileage of wire in the proportion of 7 to 8. This disproportion leads naturally to the belief that the financial difficulties had scarcely time to be put straight when they reappeared in consequence of the increase in the number of accidents caused by the aerial lines. It is true that one cannot yet say

THOMSON AND JENKIN'S AUTOMATIC CURB-SENDER.

SIMULTANEOUSLY with his invention of the mirror galvanometer in 1857, Sir William Thomson directed his attention to the problem of how to send signals through submarine cables in such a way as to diminish as far as possible the retarding effect due to the electro-static capacity of the line, the theory of which he had investigated two years before. He pointed out that the sending of currents through cables should be effected so as to make the current attain as soon as possible a strength at the receiving end sufficient to move the indicator there, and that after this the charge remaining in the cable should be removed without delay—the removal of the residual charge being effected by the application at the sending end of an electro-motive force opposite in kind to that by which the signal had been produced. This system of using two currents, one to produce the signal and the other, of opposite name and somewhat shorter duration to neutralize (as nearly as possible) the residual effect of the first, is what is known as Curb-Sending. Its object is, of course,

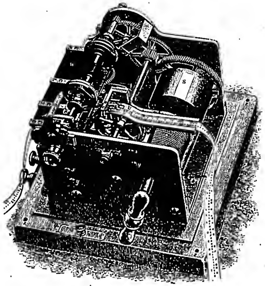

FIG. 1.

to increase the speed of signalling, and it does so by giving each signal a sharp definition, and an independence of the signals that precede and follow, which is unattainable when, as in ordinary working, each signal enters a cable already in a complicated state of charge. Simple as the principle of curb-sending is, its practical application has been found to present many difficulties. Trials have been made, but without success, to send curb-signals by means of a hand-key, the failure being no doubt due to the fact that a greater perfection of spacing is necessary than hand-sending can give. The problem has now, however, been solved, and the introduction during the past year of the Automatic Curb-Sender, under the joint patent of Sir. W. Thomson and Professor Fleeming Jenkin, is certainly one of the most important recent advances in submarine telegraphy.

Fig. 1 gives a general view of this instrument, the actual dimensions of which are about double those in the figure. The message to be transmitted is prepared beforehand by being punched on a strip of paper in right and left-hand holes corresponding to dot and dash. The paper-strip enters in front (the left-hand side in the figure)

We have lately seen some interesting trials of the articulating telephone through Dr. Muirhead's artificial cable. It is well known that this artificial line offers the closest approximation to the electrical conditions of an actual cable that has been hitherto attained; in fact these conditions are practically realised in this artificial line, and hence its success in submarine duplex working. Any mere distribution of separate condensers along a resistance circuit, as in Varley's artificial line, is at best but a very crude approximation to an actual cable; but in Muirhead's artificial line capacity and resistance are mutually blended throughout in the same manner and to the same extent as in the actual cable, of which the artificial one is an imitation. The experiments in question were made through a length of artificial cable of the type of the Direct United States Cable. The artificial cable is so constructed that the capacity can be added to the circuit or taken away from it at will. When the capacity is taken off, the circuit is of course a mere resistance circuit and comparable to a length of land-line; but when the capacity is put on, the circuit is equivalent to a length of submarine cable. In speaking by telephone through a hundred miles of this artificial D. U. S. Cable, the words were comparatively loud and distinct; in short, were the usual telephonic utterances, reminding one of the small voice of pigmies and other fabulous elves; but the instant the capacity was put on, the voice lost both power and distinctness in a remarkable degree. It appeared only half as loud as before, and dull in tone, as if the elf had receded into the distance, or had caught a severe cold and been muffled up in thistledown. To use a homlier simile it was like speaking from under a blanket. With a hundred and fifty miles of the artificial cable, while the voice was apparently as strong as ever through the resistance circuit alone, it was completely silenced by putting on the capacity. One hundred and fifty miles must not be taken, however, as the limit of the telephone's power on submarine cables; something depends on the quality of the telephone applied. But even with the best of those at present constructed, the extreme limit of articulation cannot be much beyond a hundred and fifty miles, and certainly under two hundred. Experiments have been made, we are told, at Glasgow University, through two hundred miles of Sir William Thomson's artificial cable, with successful results; but this cable is one of Varley's "test circuits," combining condensers and resistance coils, and is by no means a close approximation to an actual cable. Theory points out, and experiment verifies the fact that if the voice is allowed to dwell on a note for a sufficient time to establish, despite induction, a regular succession of the electric waves in the cable, a faint sound will be audible. Thus, singing can be heard, indistinctly it is true, but still heard, through a greater length of cable, than talking. In articulation the changes of voice are so hurried that time is not given the cable to establish the regular series of waves necessary to reproduce sound, so nothing is heard at all.

Blasting by Electricity.—The Aberdeen *Free Press* says that an experiment was made with electricity as a means of firing blasting charges in Mr. Fife's quarries at Kemnay. A huge breast of rock, calculated to weigh about 2000 tons, was bored in eleven places, charged, and fired almost simultaneously by a current of electricity, from a battery which was under the care of Mr. David Wright, electrician, Aberdeen. The huge mass was started with little noise from the report, but with a rumbling sound like that of distant thunder. A second blasting was fired the next day, and though the ground was covered with snow, and a heavy snow-storm was falling, wires extending 1500 feet in length being laid, and a current of electricity being put on, in an instant a tremendous explosion was heard, which shook the ground like an earthquake. Great masses of granite were upheaved in the air, and about 5000 tons were displaced. It is the largest blast which has ever been witnessed in these quarries, effected by means of electricity applied by a new apparatus, most ingeniously constructed.

New Telegraph Ship.—In the *Telegraphic Journal* for February 15, we announced that the directors of Hooper's Telegraph Works had ordered a steamer to be built expressly for the purpose of reducing the expense and lessening the risk of submerging telegraph cables. On Wednesday, the 11th inst., a party of scientific gentlemen assembled at Millwall Docks to inspect this new vessel. She is 350 feet in length, 55 feet beam, and 36 feet in depth, and of 5000 tons gross register, with engines of 400 nominal horse-power working up to 2000, and realises, though not intended for speed, 10½ knots an hour. Being the first vessel ever constructed entirely for telegraphic purposes, her tanks, which are only three in number—huge cylinders, 30 feet deep and 53 feet wide—so far from being a source of weakness, really strengthen the hull; while the paying-out machinery and the appliances for picking up a lost or damaged cable embrace every improvement which experience up to the present time has suggested. The vessel is now taking in 1500 miles of cable directly from the Hooper works at Millwall, belonging to the Western Telegraph Company, which is about to lay 2500 miles of cable along the east coast of South America. The work will be performed in three sections, the first, that which is now about to be despatched on board the *Hooper*, being laid from Pernambuco to Rio de Janeiro, the second from Pernambuco to St. Thomas's, and the third from Rio to Monte Video, taking in all the intervening South American ports. After inspecting the works of Hooper's Telegraph Company, the party adjourned to the vessel—a noble, though somewhat unsightly, craft—much interest being felt in the perfect electrical testing cabin, fitted up at the suggestion of Sir Wm. Thomson, who, with Mr. Latimer Clark, represented science on the occasion, and showed the means by which signalling and testing for insulation can be carried out at the same time.

Tommasi's Relay.—We recently gave an abstract of some experiments made by M. Tommasi on the Atlantic Cable taken from the *Comptes Rendus* (bulletin of the French Academy of Sciences), on authority which ought to be trustworthy. These results did not appear to us to form any practical test of the apparatus, but we gave them for what they were worth. Mr. Weaver, General Manager of the Anglo-American Telegraph Company, however, informs us that these results are erroneous, and that the relay was a complete failure. We are not surprised at this, for it ignores the essential fact of a varying zero in submarine telegraphy, and its much vaunted sensitiveness is only exhibited through resistance—induction being absent. We have condemned this relay before, and are now not sorry to be able to expose the hollowness of its pretensions for practical submarine work.

THE TELEGRAPHIC JOURNAL.
Vol. V.—No. 100.

UNDERGROUND TELEGRAPHS.

The two valuable practical papers—"Underground Telegraphs," by Mr. Willoughby Smith, and "Underground Telegraphs in France," by Mr. John Aylmer, C.E., of Paris—which were read before the Society of Telegraph Engineers at their last meeting, on the 28th ult., has served to bring again into prominence the subject of covered telegraph lines.

Taking up a statement of Mr. Prescott's which appeared in the American *Journal of the Telegraph* some six or eight months ago, that the "use of underground telegraph lines had thus far been attended with very unsatisfactory results," Mr. Willoughby Smith sought to establish, and undoubtedly succeeded in establishing, the fact that underground telegraph lines need be attended with no greater risk than open lines—nay, that were the proper material only employed, and due care taken in the execution of the work, there is no reason why covered lines should not be made as safe and durable as need be desired. The most interesting feature, however, of Mr. Willoughby Smith's communication was the argument which he brought forward against the employment of tar on gutta-percha covered wire. A covering of tarred tape is, as is well known, all but universally adopted at present as the final protective covering. This, it is alleged, is a grave mistake; for by reason of its use the insulation resistance is materially diminished, and the germs of decay which in time lead to the complete destruction of the coating are implanted in the gutta-percha. The tar ought to be abandoned, and in its place tannen, whose employment was stated to have been highly satisfactory, ought to be adopted. In the valuable address delivered some time since by Professor Abel, at the Society's opening meeting, this same subject was dealt with, and the state of our knowledge with reference to the causes of decay in gutta-percha was shown to be crude in the extreme.

Granting, however, that tar is an objectionable feature in the manufacture of gutta-percha covered wire, was there not some point in what was remarked by one of the speakers in the animated discussion which followed, that surely then Chatterton's Compound was not altogether an unmixed advantage? Chatterton's Compound consists of one part of Stockholm tar to one of resin and three of gutta-percha, and has long been regarded as the panacea for every evil that could befal gutta-percha covered wires. No coating can be considered complete, it is said, no two can be welded homogeneously together without Chatterton's Compound; and if tar is the *bête noir* it is now stated to be, what becomes of the influence of Chatterton's Compound? It is all very well to be told, as Mr. Willoughby Smith told us the other evening, that "in the Compound the sting of the tar was taken out." It is a pity that the same process of sting-abstraction could not be applied with equal success to the tar in the tape. No, we shall wait for a few further data and a few additional experiments before condemning the tar wholesale and making it accountable for all the mischief; and we will be content to look for the deterioration of the gutta-percha, to a very great extent, at least, in the cheap and consequently indifferent material which has never been properly tested, and hasty manufacture over which no efficient check has yet been introduced.

No one will now attempt to call in question the possibility of manufacturing really good covered wires: the battle of india-rubber and gutta-percha need not be fought over again, for the improvements effected in the latter have been so decided of recent years, that its position is well-nigh unassailable by its old rival. If danger is to be anticipated from any quarter, paraffine and the products of paraffine will probably show it the most dangerous front. Meanwhile, every one will admit that covered wires as good as need be looked for in the existing state of our knowledge can without difficulty be manufactured, and no one will deny that their laying is a matter which requires nothing more than care to be attended with success. When, therefore, the need for underground telegraphs on a more extended scale than at present does arise either from the crowded state of the open lines on every available route or from an alternative channel being thought desirable, we may rest perfectly satisfied that our telegraph engineers and electricians will be quite equal to the occasion; and if the day when that need does arise is even but a short way off, they may as likely as not turn round and regard our manner of doing things in much the same light as we regard the now antiquated attempts of but a few years back in the matter of covered lines.

We have no space at our command to go into Mr. Aylmer's paper at present, but we shall again return to it. His communication was one of great practical value, bringing forward many new and striking facts as to how these things are done in Paris.

9 Jan 76

Telegraph Stations in Mid-Ocean.—Several foreign naval powers are directing their attention to the practicability of establishing telegraph stations in mid-ocean, by which messages can be sent from any part of the sea along the line of the cable to the terminal points on shore, and *vice versa*, so that communication with ironclads, mail steamers and other vessels when out at sea, may be established. The invention consists of a hollow sectional column, with a base plate attached by ball and socket joint, which column is lowered into the water, and anchored rigidly to the ground. The branch cable is coupled to the main cable, and carried along the column to the surface of the water, to be there connected with instruments on board the vessels. By this invention it is proposed to control naval and strategical movements, whilst a ship in distress could communicate her exact position, the nature of disasters, and thus procure assistance.

THE TELEGRAPHIC JOURNAL.

Vol. IV.—No. 82.

REPAIRING SHIPS.

We have once or twice alluded to the necessity of Submarine Telegraph Companies possessing properly fitted steamers for the repair and maintenance of their lines. Yet we can hardly find fault with private companies for not having cable ships of their own, when our own Government sets the example of false economy by remaining entirely dependent on the casual hire of a steamer for the repair and maintenance of their cables.

The Electric Telegraph Company, whose lines formed the greater portion of the system transferred to the Post-office, had a repairing ship of their own, and this ship was made over to the Government, but, being worn out, was condemned, and has never been replaced; and although designs for a new ship have been made and approved, and tenders sent out some three times, the Lords of the Treasury have each time repented of their step so far, and have retreated with buttoned-up pockets. The consequence has been that, under pressure of broken-down communications, a fully fitted ship has to be hired, and the expense that has been incurred by chartering ships for each repairing expedition, as compared with the cost of buying and maintaining one, must be very great, and would form an interesting subject for a question in the House of Commons. The ships hired are generally larger than necessary for the work; indeed, for some work, their size is a positive disadvantage. But, besides this, the hiring of a ship must always be preceded by negociations which, even between companies or firms, must take time. With all the encumbrance of government official correspondence this must still be greater, and during this period communication is stopped. Moreover, the case might easily occur that no fully fitted cable ship was disposable, as they are not so very numerous, and thus the government would have to hire a steamer and fit her out, an operation that would occupy several weeks.

Nearly all companies and administrations having submarine cables have learnt, sooner or later, by their own experience, when they have ignored the experience of others, the absolute necessity of having at their constant disposal a ship ready to repair and maintain their lines, and the Government have simply gone a step backwards from the preceding owners of the telegraphs in thus neglecting to supply the place of the *Monarch*.

The "*Monarch*"—the "*old Monarch*," or "poor old *Monarch*," as she was at last affectionately called, was *the* first permanent repairing ship. She was a paddle-wheel wooden steamer of 427 gross tonnage, built in 1830, and bought by the International Telegraph Company in 1853, and from her were laid the first cables between England and Holland. In 1854, she was fitted with the first drum "Picking-up" gear, and in her the first systematic operations connected with the repair of cables were executed. She continued to be employed at this work until the transfer of the telegraphs to the Government, and soon after was condemned. The Submarine Telegraph Company, who for some time employed Liverpool tugs, at last built the *Lady Carmichael*, paddle-wheel steamer. The Indian Government, in 1863, bought the *Charente*, a small screw-steamer, re-named her the *Amberwitch*, and fitted her as a repairing ship for the Persian gulf cable, where she has been employed ever since. The Anglo-American Company bought the *Robert Lowe*, since wrecked, which was followed by the *Minin*, their present repairing ship. The Eastern Company possess the *Chiltern* and the *Hawk*. The Eastern Extension Company have now the *Agnes* and the *Edinburgh*. The Great Northern Company possess the *Œrsted*; the Western Brazilian Company the *Norseman*; and the West India and Panama, the *Investigator*. The American International Ocean Company possess the *Professor Morse* (formerly the *Suffolk*), and the French Government had for some time a small steamer, called the *Ampère*, which has since been replaced by a larger vessel called the *Charente*. The Direct United States Company have no repairing ship of their own, but employ the *Faraday*, and the Anglo-American Company, besides their permanent ship the *Minia*, are now employing the *Hibernia*.

It will be seen, therefore, that the necessity for repairing ships has become generally acknowledged. Indeed, with the exception of the Brazilian Submarine Company, our own Government are the only important administration possessing cables without the means of dispatching a ship to repair a fault within a few hours after the interruption of a cable.

For a perfect repairing ship, many qualities are required, but, perhaps, the most important is that of being capable of turning without "way" through the water. Disconnecting paddles effect this, but if there are only a pair of engines, there is the disadvantage of the dead point, besides the cumbrous nature of the disconnecting gear if the ship is large. A pair of engines to each wheel overcomes the dead point question, but this increases the machinery. The plan adopted by Mr. Siemens, in the *Faraday*, of twin screws, the shafts of which converge towards a point astern of the ship, is

with Panama, on the Pacific coast, by a submarine cable, has, after protracted negotiations, been abandoned by mutual consent, it having been found impracticable to obtain the necessary landing rights at Panama, except on terms which the Company could not with advantage accept. The working agreement that existed between this Company and Mr. Henley, of North Woolwich, and which lapsed through the suspension of Mr. Henley, has been renewed with a Company formed for the purpose of carrying on his extensive works, on terms which, it is believed, will be advantageous to both parties."

CHINA.

Shortly after the establishment of the Torpedo College at Foochow, His Excellency Li Hung Chang, Viceroy of Cheli, First Guardian of the Emperor, &c., &c., sent an official request that Mr. J. A. Betts, the director of the college, should proceed to Tientsin with the whole of the torpedo apparatus just received from England, to carry out a series of experiments before His Excellency. The *Chi-Ngan*, one of the Chinese gunboats, was ordered to convey Mr. Betts, and the stores, to the latter port, and during the month of October last a lengthened and very successful series of experiments in telegraphy and torpedo warfare were carried out in His Excellency's presence.

Telegraphic circuits were established, and a complete system of torpedo defence fully illustrated by the explosion of numerous torpedoes in the Pei-ho, near Tientsin. Further experiments with heavy charges were shown at the Taku Forts. His excellency lent his own steam launch for these trials, and expressed himself much pleased. The electro-contact torpedoes excited great interest and were much admired.

Mr. Betts exhibited the Royal Engineers' system of telegraphing by "Walker's Lime-light" on the city walls of Tientsin; this seemed to create a deal of astonishment among the Chinese, and although at a late hour of the night, and bitterly cold, caused an immense crowd to assemble.

Mr. Betts will return to Tientsin in the spring, when he will at once commence drawing up a system of torpedo defence for the Taku and Peh-tung Forts, which are also to be connected by a line of telegraphs.

M. Duchemin has found that nickel, deposited by electricity on the magnets of compasses, preserves them from oxidation. He deposited in this way a layer of nickel on several rings of one of his circular compasses, keeping two concentric circles free from the operation. This compass was put on board a vessel which went round the world. The rings covered with nickel preserved their polish, but the others were completely rusty. The magnetic power of the nickelized rings had been exerted with difficulty, no doubt on account of the magnetic property of the nickel. — *Comptes Rendus de l'Academie des Sciences*, Nov. 15, 1875.

Proceedings of Societies.

THE SOCIETY OF TELEGRAPH ENGINEERS.

Contributions to the Theory of Submerging and Testing Submarine Telegraphs.

By Dr. WERNER SIEMENS.

The starting point of submarine telegraphy is to be found in the subterranean lines constructed in Prussia during the years 1847—1852. Before that time, it is true, attempts had been made to insulate wires with glass tubes, caoutchouc, &c., for use as underground lines. Experiments on a somewhat extensive scale by Jacobi* at St. Petersburg in the year 1842 deserve mention; but these attempts failed.

In the year 1846 the author suggested to the Prussian government the use of gutta-percha as insulating material, this gum having then recently become known in Europe. Its remarkable plasticity and insulating property appeared to render it very suitable to the purpose in question, but neither the experiments made at Berlin, nor those carried out simultaneously in England, were attended with satisfactory results; for the joints of the gutta-percha (which was rolled round the wire), gave way after a short time. At last, in the year 1847, the problem found its solution in a covering machine, constructed and used by the author and Mr. Halske, by means of which the gutta-percha, rendered plastic by heat, is pressed round the wire without any seaming.

During the subsequent years an extensive network of underground lines, insulated with gutta-percha pressed round the conducting wires, was somewhat too hastily and inconsiderately introduced in North Germany and Russia; although those lines were far from durable (particularly because the conducting wires, to save expense, were imbedded in the ground without external protection, and at too small a depth), they afforded opportunity of gaining practical knowledge for the construction and maintenance of such insulated conductors, and of studying their physical properties. But it was reserved for English enterprise to convert the knowledge and experience thus gained to practical account in a sphere where there was no competition with cheaper overground lines, that is to say, to submarine telegraphy.

As early as 1850, Mr. Brett laid a single gutta-percha-covered copper wire across the Channel between Dover and Calais. As might be expected, this became useless; but in 1851, Mr. Brett substituted a conducting wire insulated with gutta-percha, and protected externally by a sheathing of iron wires. This was the first practical submarine cable.

No great difficulties were encountered in laying these cables in the comparatively shallow waters of the Channel. But when later Mr. Brett endeavoured to lay such cables in seas of greater depth he failed, because the forces brought into play in laying deep sea cables were not yet recognised, and, consequently, the necessary precautions had not been taken. The laying of the first successful deep sea cable between Cagliari and Bona, in the year 1857, in which the author

The new joint for gutta-percha covered wires, devised by Mr. Willoughby Smith, is formed by removing the coatings from the two ends to be united, and joining the cleaned wires by what is technically known as the "bell-hanger's twist." No solder is necessary. The twist is then warmed slightly, and covered with a rough coating of insulating "compound," somewhat thicker than the original diameter of the wire. The joint, while warm, is placed in the lower half of a small wooden block, about three inches long and one inch wide, fitted internally with a groove for the wire, widening in the middle into a niche, about an inch and a half in length, for the reception of the compound-covered joint. While the compound is yet warm, the upper half of the mould—in shape corresponding exactly with the lower one—is placed on the top, and by means of a clamp, screwed down until the two wooden surfaces are pressed firmly together. While in this position they are permanently fixed by half-a-dozen ordinary brass screws, and, the compound having hardened, the clamp is removed and the joint complete. The principal advantage claimed for the new joint is its simplicity, as it can be readily made by comparatively experienced hands in about ten minutes. The cost is reduced to a very low figure, and, by means of the wooden cover, all danger of leakage or separation of the wires through bending is obviated.

Tel Journ. Apr 15 1877
Tel Journ Apl 15 1877

A paper on "Underground Telegraphs" was then read by the author, Mr. Willoughby Smith, a *resumé* of which is appended:—

UNDERGROUND TELEGRAPHS.

In the *Journal of the Telegraph*, dated September 1, 1876, under the heading of "An Interesting Statement," after recapitulating what had been done in England in 1852-3, appeared the following statement: "The most experienced telegraph engineers and electricians of all countries in which underground wires have been used, are united in the opinion that thus far at least their use has been attended with very unsatisfactory results, and that no method of construction yet devised has maintained underground wires in working order for any length of time."

Mr. Smith was of opinion that that statement, emanating, as he believed it to have done, from an American gentleman of high authority, ought not to pass unchallenged. True it was that the failure which followed the laying down of the system of underground wires in England during the above-mentioned years gave a blow to the prospects of subterranean lines, from which they have never yet recovered; but, on the other hand, when we take into consideration the manner in which the wires were then made and the system carried out, we can feel no surprise at their early failure, and our only wonder can be that they lasted so long as they did.

In 1853 four of the then largest telegraph companies were engaged in the manufacture of the wire, which they subsequently laid in the later part of the year between London and most of the large towns in England. In June of the same year part of the factory of one company which supplied most of the wires was destroyed by fire, which did not help matters, inasmuch as each company, in their anxiety to complete their respective lines, allowed a laxity of supervision which would not otherwise have existed. Coal-tar, naphtha, and other solvents of gutta-percha were applied between the coatings to effect adhesion, but which evidently exercised a deleterious action upon the gutta-percha.

In 1857 Mr. Smith introduced an adhesive mixture for this purpose, consisting of 60 per cent. of Stockholm tar, 20 per cent. of resin, and 20 per cent. of gutta-percha, at present known as Chatterton's compound, and this has been almost unexceptionally employed since that date, and with every success.

The conductor employed was a solid copper wire, weighing 63 lb. to the mile, and of very inferior conducting power; some lengths have since been found to possess only 18 per cent. of the conductivity of pure copper.

The system of testing employed was very rough. The wire was immersed in water at no specified temperature, one end left free, and the other connected to one terminal of a sand battery of 360 cells, and with what would now be considered a very dull vertical galvanometer; if the deflections so obtained were not high, the coil was considered good, and delivery soon followed. When subsequently faults were discovered, the pernicious system of picking the wires was resorted to.

The manner of laying the wire was equally detrimental to its longevity. One company laid part of their wire without any protection whatever in the six-foot of a railway, and the remainder were laid in square *creosoted* wooden blocks, from six to ten feet in length, with a groove of sufficient size to contain them. Boards of the same material were then *nailed* on after the wire had been laid, and the trench in which the whole had been placed was then filled in. The nails penetrated the gutta-percha in many places, and so numerous were faults of this nature that nails had to be abandoned, and the troughs were bound with wire instead.

Another company laid their wires just as they received them from the manufactory, in a somewhat similar manner, after having passed them through a bath of *hot coal-tar*, and then allowed them to dry in the sun, suspended from bars of wood.

In 1861 Mr. Smith introduced a great improvement upon the tarring process, viz., that known as the "wet serving." He advocated the use of an external conducting serving in the form of tanned hemp, inasmuch as tar, being an insulator, possesses the property of temporarily concealing the presence of a fault which must ultimately develop itself. Another and still greater argument against the use of tar is the prejudicial effect exercised by it on the durability of any gutta-percha covered wire, especially when exposed to atmospheric influences. Since that date the use of tar in connection with submarine cables ceased, though it still continues to be employed in the case of subterranean lines, and it was with a view to induce its discontinuance in the latter also that Mr. Smith undertook the following experiments:—

Three separate samples of what was said to be pure Stockholm tar were procured from three different sources, and three lengths, 1,000 yards each, of core, containing 107 lb. of copper and 140 lb. of gutta-percha per nautical mile, were immersed, one length in each sample. In the coil marked No. 1, the tar was kept at a uniform temperature of 90° Faht. while the coil was immersed in it. Daily tests of the resistance of the gutta-percha were taken, and the results carefully noted. The fall in its resistance decreased daily. From June 8 to November 21 the resistance had fallen from 62 to 1·25 megohms per knot. The coil was then cleansed from the tar and immersed in water, which was kept at 90°. From November 27 until March 5 the resistance gradually *increased* from 1·257 to 26·96 megohms per knot, and then gradually began to fall, and on May 20 its resistance was 2·237 megohms per knot. For three years this core remained immersed in water at no regular temperature. The water was then kept at 75° Faht. for twenty-four hours, and the resistance was then found to be *nil*. The coil was then divided into four equal lengths, and each length gave the same result, showing that the resistance was destroyed by no local fault, but was general throughout the entire length.

Coil marked No. 2. In this experiment the conditions were precisely the same as in the previous one, with the exception that the tar was not kept at an uniform temperature, but varied during the experiment, the minimum being 60° and the maximum 68° Faht. During four years the resistance gradually decreased from 13·98 to 4·76 megohms per knot. After being cleansed from the tar, and immersed in water at a temperature of 75° degrees for twenty-four hours, the resistance increased to 11·43 megohms per knot. This coil was divided also into four equal lengths, and the result showed a depreciation throughout the coil.

Coil marked No. 3. This experiment was conducted precisely the same as with coil marked No. 1. From June 12 to November 21 the resistance gradually fell from 74·4 to 0·587 megohms per knot. It was then thoroughly cleansed from the tar and immersed in water. From November 27 to December 22 the resistance gradually increased to 3·55 megohms per knot, and then began to decrease, and at the end of one month its resistance was *nil*. The depreciation was uniform throughout the entire length. When one end of the conductor was connected to one terminal of an induction coil, and a wire from the other terminal to which was attached a piece of moist sponge was passed near the surface of the gutta-percha, it was instructive to see the current, in the form of a luminous brush, passing freely through the gutta-percha; and at distances varying from seven to nine inches the current broke through the gutta-percha with force, leaving a hole resembling a puncture made by a small blunt instrument. No such effects were produced on a length of the same core which had not been in tar, but kept at the same temperature in water, when subjected to precisely the same treatment. It will be seen that the action of the tar on the electrical qualities of the gutta-percha was more rapid on coil 3 than on coil 1. Although the tar used with coil 3 was said to be from Stockholm, it was much inferior in quality to the other two samples. It will also be seen that the higher the temperature the quicker the effect on the gutta-percha. Coal-tar has a much quicker effect than Stockholm-tar, and coal-tar naphtha very quickly destroys its insulating properties, and disintegrates the gutta-percha, causing it to "crumble like old putty."

At the close of the last session Mr. Smith brought forward a new form of joint of which he had great hopes, and from which he had already succeeded in getting very high insulation; but he had at that time only two months' experience of its mechanical and electrical properties. Since that time, however, it had been regularly submitted to severe tests, and he could now speak of it with more confidence. He had at first advocated the use of Chatterton's Compound in the formation of that joint; but however suited that compound may be for the purposes for which it is employed, he preferred at present to use a compound of gutta-percha and resin alone. Mr. Smith also exhibited several lengths of wire containing joints, and stated the insulation resistance of each length in megohms; also two test boxes—one to contain twenty and the other over a hundred joints.

Mr. Smith also proposed that the size of the wire at present in use should be increased comparatively, as the thin coating of gutta-percha causes the wire to be in danger of receiving mechanical injury when handled.

In conclusion, Mr. Willoughby Smith expressed his opinion that if proper care were taken in the testing of the wire and its subsequent mechanical protection, we possess no data which point to failure; on the contrary, as subterranean wires come more and more into favour, all the evidence which we can at the present gather points unmistakably to success in this direction.

An interesting paper was then read upon "The Underground Telegraphs in France" by Mr. John Aylmer, the Society's Local Honorary Secretary in that country. We are prevented from entering to any extent into the ingenious contrivances mentioned in this paper beyond the fact that in Paris the underground system is chiefly placed in an extensive network of sewers beneath the streets of that city; a cable is made the size depending upon the number of wires required, and laid in leaden piping supported along the walls of these sewers.

When the piping is completed a carrier, to which is attached a light cord, is sent through by pneumatic pressure. When the carrier arrives at the distant end of the section it is removed, and the cord which it has brought through used to pull in a wire, which in its turn pulls in the cable.

The discussion on these papers was taken up by Messrs. Schramm, Truman, and Treuenfeld, Mr. W. H. Preece, Sir Charles Bright, the President, and Mr. Willoughby Smith.

Mr. Schramm described the form of subterranean line employed by the German government.

Mr. Truman asked why it was that if tar was so injurious to the durability, the compound mentioned by Mr. Smith, in which tar existed to the extent of 60 per cent., was not also injurious, and expressed his opinion that it was so, and that he thought the time was not far distant when cable-core would be formed by a copper strand covered by a single coating of gutta-percha, inasmuch as the difficulties which presented themselves in the early days of cable manufacture, and which necessitated the building up of the core, have long since been obviated.

Mr. W. H. Preece gave an entertaining history of tar in connection with gutta-percha covered wires, mentioning that the chief inducement offered by the use of tar, which ended in its subsequent employment, was the fact of its filling up any fissures in the gutta-percha with an insulating fluid.

Mr. Treuenfeld remarked that it would be interesting to know whether tar formed any known chemical reaction in the presence of gutta-percha.

Sir Charles Bright gave an interesting historical account of some of the lines mentioned in Mr. Willoughby Smith's paper which he himself laid down.

The President then stated that, with reference to the question raised by Mr. Treuenfeld, the actual chemical action which takes place when tar and gutta-percha are in contact are somewhat difficult to determine, since tar itself is not a simple chemical substance but a mixture of substances, all possessing more or less a solvent action on the percha, and also that no two samples of tar are chemically alike.

Mr. Willoughby Smith, having replied to his paper, a vote of thanks was unanimously accorded on the motion of the president to the authors for their valuable papers.

The meeting then adjourned.

We understand that Mr. Sivewright is about to proceed to the Cape Colony to investigate the working of the telegraph system at that place. From his experience in the Home Postal Telegraph Service, Mr. Sivewright is eminently fitted for such a task.

15

and Manchester have been eradicated in the present work; and the main causes of failure in the British Company's road wires will, it is hoped, be also avoided. This is a question which time alone can solve. This is, the author believes, the first time any severe and searching system of testing has been adopted in any such work. The line selected for laying down a series of underground wires was from Liverpool to Manchester. The survey for the route was made by Lieutenant Ramsay, of the Royal Engineers, under whose charge also the pipes were laid. The new work commenced where the street work in Liverpool ceased, and proceeded along the main road in iron pipes for some distance,—thence to Warrington by earthenware pipes, and thence in a mixture of earthenware pipes and iron pipes to Manchester. About seven miles from Liverpool the ground generally lies very low, and that part of the country is celebrated for its rainfall. On a considerable proportion of the route the water lies in the pipes even in summer. A more favourable situation for gutta-percha covered wires can not well be imagined. The various forms of cables hitherto used for underground work have differed in the size of the wires, but very little in their construction. Of the previous cables there may be said to be two forms, the general form being the straight wire cables consisting of a number of single wires covered with tarred tapes and bound together, forming a "cable" so called. The second, the form used by Mr. Henley in the works carried out by him, consisted of a number of plain gutta-percha covered wires laid parallel to each other, and being of the same length, and served over with tarred tape or some other preparation. The cables used in the present work were made by the Gutta-Percha Company, and were entirely different in their construction. They were of the true cable pattern. The core itself consisted of gutta-percha wire No. 7 gauge; copper wire No. 18 gauge, 39 lbs. to the mile; gutta-percha 46 lbs. per mile. It was manufactured in the ordinary way, being covered with two coats of compound, alternating with two coats of gutta-percha wrapping. The total weight was 85 lbs. per statute mile. The core, as it was manufactured, was cut off into special lengths as the cable required. The wires so cut off were wound on bobbins. The cables which were made up were subsequently passed through a bath of cold Stockholm tar in which was a quantity of fine cork-dust, to give the tar more solidity. After receiving this tar, the cable received two servings of tarred tape laid on in opposite directions. The tape was specially manufactured for the purpose. The cables, when ready for drawing in, were placed upon drums revolving on a stout frame, and at a convenient distance from the mouth of the pipe to avoid friction against the various points. Close to the mouth of the pipe was placed a wooden roller so as to prevent any friction against the edges of the pipe. After the cables had been drawn, and the wires numbered, the several ends were opened out, cleaned, and properly prepared for the jointers, who followed on as soon as they had completed the preceding set of joints. Each jointer had an assistant. The men employed at this work were more intelligent than the ordinary labourers. It was necessary that, as the work extended over open roads, a travelling testing-van should be constructed for the purpose not only of carrying the instruments and battery, but of affording accommodation for more than one person, and, indeed, acting as an office and travelling-carriage. A van admirably adapted for this service was designed by the author, and used in the work. The electrical apparatus consisted of 100 No. 3 Leclanché cells specially mounted on well-insulated tops. As the tests of the cable were to be almost identical with the ordinary tests of the submarine cable, the insulation of batteries and instruments was carefully secured. It being necessary to test the various joints throughout the work, a special joint-prop, with ebonite feet, was made for the purpose of placing inside the joint-boxes. For carrying out the tests, it was necessary to "make earth" wherever the van stopped. For this purpose a copper plate was used for places where water was at hand; and a long iron tube pointed at the bottom end, and with a screw connection for the earth wire at the top. This was driven into the ground at the dampest places, and answered admirably. The proper method of testing the joints was a question of some difficulty. After a great deal of consideration, and the abandonment of several plans, the author succeeded in devising a system which, he believes, will be found the best for adoption in all future underground works. The cables were tested in sections, and, immediately afterwards, all the joints of that section. The peculiarity of this plan is in so dividing the cables into sections varying in length, and in so looping the wires at the two ends, that a continuous circuit is formed. Any wire, therefore, in a joint-box will at once present the two ends of this continuous circuit, and render any tests of whatever kind perfectly easy. Condemned joints were replaced, and, as a proof of the improved insulation obtained by cutting out the bad joints, a statement may be given of the insulation resistance of the loops of two sections before and after the joints were cut out. In one section, the mean insulation-resistance before the joints were cut out was 111; afterwards, 481. In the other section, the mean of the fourteen wires throughout the section was 110. After the condemned joints had been cut out and replaced by good joints, the mean grew to 480. After a section had been passed, it was perfectly joined on to the next, and so on; but no section was added until the previous one had been found to be still in good condition. Of the various operations connected with practical telegraphy, there is scarcely one so important, or requiring so much practice and experience, as the making of the joints in a gutta-percha covered wire; and this operation was the most difficult throughout the work. Joints had to be condemned wholesale. Of the causes tending to bad joints, one is dissimilarity in the materials employed. Another cause was physical unfitness on the part of the workman. A greasy sweat sometimes issues from the pores of the hand, and it is easy to see that, as the joint requires frequent handling, this fact will tend towards bad jointing. The inclemency of the weather will sometimes interfere with the operation. And, lastly, the absence of cleanliness is one of the most serious defects a jointer can possess, and one which, more than anything else, is the cause of bad joints. The faults which beginners usually exhibit are simply the result of a want of experience, and this want practice alone can meet.

The Chairman said that the paper was one which would be sure to elicit a warm discussion, but the remarks must necessarily be somewhat curtailed, as a special meeting for altering the rules of the society was to take place after the present proceedings. He then invited Mr. Graves to open the discussion, he having had a great deal of experience as to the causes of failure on the Great Northern and North Eastern lines.

Mr. Graves said that perhaps the causes of failure were, throughout, the same—simply the neglect of the conditions which Mr. Preece had stated to be essential to the manufacture of a good joint. The joints, some years ago, were made without the slightest consideration of the conditions that were necessary to produce anything like a perfect result. To begin with, attempts were made to unite thick pieces of gutta-percha, simply by bringing together two portions of the material, very often imperfectly heated, and in a different state of temperature in relation to each other, and also frequently consisting of different manufactures.

The President said the first subject on the agenda was the adjourned discussion on "*Underground Telegraphs.*"

Major Webber said the very interesting paper read at a previous meeting by Mr. George Preece gave a most complete account of probably the most perfect underground telegraph line that had ever been laid down in this country, but he said very little of the history of the past maintenance of underground telegraphs and the experience of those connected with their construction. He (Major Webber) then ventured to remark that the history of underground telegraphs, so far as they knew, was not such as to make it desirable to perpetuate the use of covered wires carried underground; but he only did so in order that perhaps others who had had experience of it in other countries would tell them something about it. Seeing that the paper for the evening was likely to be of so much greater interest to the meeting than anything he was likely to say on the subject of underground telegraphs, he would not take up their time, but hoped that the subject would be again brought forward on some future occasion.

Mr. R. S. Culley said the great difficulty with underground telegraphs, so far as he knew, had been in the joints. Mr. Preece took especial care with his joints, and they appeared to stand very well indeed; but it was almost impossible to afford the time that was necessary to make the joints in the perfect manner that Mr. Preece had done. There were 250 or 280 gutta-percha wires running through the Holborn viaduct, and 280 wires jointed on Mr. Preece's system would take very likely 280 half days to complete. They were consequently obliged to use a much rougher mode of making the joints, which, in competent hands, was generally fairly successful. But still, though they tried to teach the men to joint, they found that their wires were constantly giving more or less trouble at the joints, not so much in London as in the country. In London the joints stood tolerably well, because they had men who had been making joints, some of them, for these 20 years. If any one could invent a method of jointing gutta-percha wire that could be done more quickly than the kneading method, and yet would give a fair joint that would stand, and a fair amount of insulation, say ten millions, it would be a very great advantage.

Mr. Truman said he believed he was in a position to say that such a joint could be made,—a joint of perfectly solid gutta-percha, without any appreciable loss of insulation,—and that such a joint could be made in the course of perhaps 20 minutes. He had some experience in the use of gutta-percha, and for many years it had been his hobby to use all the knowledge he had for the purpose of advancing its use for telegraph purposes, one of his main objects being to improve the joint. The great impediment in the way of a perfect joint was the compound, for they could not manipulate the gutta-percha properly when they had another substance intervening between the layers. He believed that a solid gutta-percha covering without any compound was what they wanted, and at some future period he should be happy to lay before the Society any knowledge he might have upon the subject.

Mr. R. S. Culley read a paper on "*Duplex Telegraphy.*" He stated that the details of the system are too minute to be dealt with successfully in a paper before an audience. The first questions which are asked are, How do the currents pass one another in line wire? and if they do pass, how is it they do not interfere one with the other? Telegraphists are too well aware that when two stations dispute for the possession of a circuit, the signals of each station are affected by those of the other, and neither station can read a word. In the case of the single needle, it is found that when the direction of the two currents is the same, the needle moves more strongly than when the current is simply from its own battery; and when the direction of the two currents differs, the needle scarcely moves at all. As the effect of this is entire confusion of signals, they must see whether it would not be posible to unravel this confusion, and if so, they would resolve the problem of the duplex. Suppose, first, that each sending-clerk knows the force with which his needle ought to strike the stops by the action of his own current, so that it is just possible for him to see when the distant station, B, sends a current in the same direction as he is doing at A, because at that moment A's needle strikes the stops more strongly than usual. Let A read that movement as a signal sent by B in the same direction as his own. Secondly, if B tries to move A's needle in the opposite direction, it will strike the stops less strongly, or perhaps will only move half-way to the stops. Let A read this as a movement in the opposite direction to his own. If it were possible, then, to have two clerks, one standing by the key and watching the way the sender moved his hand, and at the same time watching the movement of the needle and the strength of the deflection, it would be possible for him to know what signal the distant station sent. The author does not mean to say that, practically, anyone could read in this way, but it is just possible the direction of signals sent by the distant station might be distinguished. Thus it would be seen that, if by any means they could arrange so that a station's outgoing current could not affect his own needle, it would leave his dial free to show only the effect produced by the incoming current, and then the signals sent by the two stations would be separate one from the other. How then can each instrument be so connected that another sender shall affect his own needle, and yet so that his coil shall always remain in circuit to receive the current of the distant station? The author proceeds in his paper to consider what occurs in testing a line wire simultaneously between two stations for resistance with a differential galvanometer. He shows by actual experiment that so long as the resistance of the rheostat at each end remains equal to that of the circuit tested, each station will see the current sent by the other, although neither of them can see his own current. The reason is this; the current sent by each station is divided equally between the line wire and the rheostat. The two resistances being equal, the currents in the two coils are equal, and, therefore, the outgoing current does not move the sending station signal. The two currents do not pass one another as has been imagined; but when both stations signal at the same time, the current sent by either station acts upon the distant instrument by determining, for the moment, whether the line or the rheostat shall offer the easier path for the current originating there. In studying the effects produced by the varying positions of the key at each end of the circuit, the author states that it is better to take the case of a single instrument working by a single current, such as a Sauger or a Morse. In working one of these instruments the batteries are generally connected, so that when both keys are pressed at the same time, the currents flow in the same direction and assist one another, and when either station signals separately the currents are divided. But if the distant station depresses his key, he puts a zinc current on the line that assists the current in the line, but does not assist the current in the rheostat; therefore the strength of the current in the line is much greater, perhaps double that in the rheostat, and the needle of the distant instrument moves because the resistance of the line is virtually decreased, or the effect is the same as that of decreasing the resistance of the line. In the case of the single needle, if A sends a positive current, while B sends a negative current, the two are in the same

Submarine Key of M. Sommati.

THE object is to neutralise, at each emission of the current, the effects of charge of the cable. (M. Sommoti applies the principle of it, also, to Siemens relays, employed in translations, and Hughes apparatus, working on long lines.) A reversing battery is, by means of an auxiliary lever, made to act momentarily when the key is returning to the state of rest, and before it has reached it. The editor considers the arrangement will probably work well on short submarine cables, not on long ones. The idea of the small auxiliary lever bringing into action a reversing battery is not new.

A SUBMERGED TORPEDO BOAT.—The Rev. G. W. Garrett, Manchester, has invented a torpedo-boat which is capable of sailing under water and fixing torpedoes to a ship's hull. It can be propelled by the men on board, by compressed air, or other motive power, and is lighted by electricity. Electric beams can also be directed in any direction under water. The supply of air taken in for the use of the men is purified by a very ingenious process, which is also applicable to diving bells, and enables the men to remain several hours submerged. A successful trial of this boat was made recently at the Birkenhead docks. While on this subject we may mention that a new and very devastating torpedo has been invented by Mr. Ericsson.

759. "Telegraph Cables." F. LAMBERT. Dated February 23, 1878. 6d. This consists in protecting cables from teredo ravages or rusting, by sheathing it in the material called mineral wool, slag wool, or silicate cotton, with a suitable agglutinating material such as pitch, tar, oils, india-rubber, &c., capable of resisting the action of water. The protection is applied either as an outer coating, or as a tape wound spirally round the core, or as serving in lieu of the ordinary hemp serving.

THE INTERCOLONIAL CABLE.—An agreement for the construction of a cable from New Zealand to New South Wales, and from Normantown to Singapore, has been signed by the conference representatives of New South Wales, Queensland, and New Zealand. The agreement is to the effect that these colonies shall guarantee five per cent upon one million pounds for thirty-five years, on condition that the cables are constructed for that sum. Receipts of over twelve thousand pounds go to reduce the guarantee. The arrangement will effect a reduction of thirty per cent on the rates charged for messages *via* Singapore, as compared with the Java cable rates. Mr. Audley Coote, agent for the Indo-European, Atlantic, and other leading telegraphic companies interested in the construction of the cable, has been instructed to accept the proposals of the delegates for the construction of the line. The tariff of charges is as follows:—From New Zealand to New South Wales, not to exceed 15s. for twenty words, and 9d. for each additional word; from Normantown to Singapore, 40s. for twenty words, and 2s. for each additional word.

UNDERGROUND TELEGRAPHS.—STREET WORK OF LONDON.†

By C. FLEETWOOD.

THE following is an abstract of this paper:—From the original five wires used by Cooke and Wheatstone in July, 1837, to test their five-needle telegraph, the system has increased latterly with rapid strides, 750 wires at the present time entering the central station, St. Martin's-le-Grand, alone, with a total mileage of over 3,500 miles of wire.

On the successful issue of the Cooke and Wheatstone Telegraph, five wires were placed underground in lead pipes between Paddington and Drayton, but became defective in 1841, and were replaced by overground wires on posts.

In 1846, on the incorporation of the Electric and International Company, the lines erected by Mr. Cooke were led by wires in iron pipes to the first office in London, 345, Strand. In the following year the system was extended underground to the new central station, Founder's Court, Lothbury. The total system of the Company at that time reached 1,500 miles, less than one-half of the present street work in London alone.

The length of pipes underground now is 110 miles, consisting of five trunk lines, radiating from the central station, St. Martin's-le-Grand, to the following points:—Hounslow, Clapham Common, New Cross, Maryland Point, Stratford, Bayley's Lane, Stamford Hill, East End, Finchley, north end of Primrose Hill Tunnel, and Harrow Road.

At the central station the whole 700 wires are carried up the interior of the building, and terminate on a test box, where each wire is numbered. Provision has been made on this box for 500 wires from the west, and a corresponding number from the east, a total of 1,000 in all.

A 4-inch pipe will hold 100 wires, and a 3-inch 72. The pipes are 9 feet long, and previous to being laid, are well cleansed inside.

The socket joints are made same as in gas or water-pipe joint.

In marking out the route, the footpath is generally chosen; the pipes are laid under the pavement, it being more accessible than the roadway.

Flush boxes, 2 feet 6 inches long, 11 inches wide, and 1 foot deep, are fixed 50 and, in some cases 100 yards apart. As the pipes are laid an iron wire is threaded, by which the cables are hauled through.

The cables are sent out in lengths of 400 yards. On arrival at the place where it is to be used about 6 inches of percha is trimmed off the end of each wire, and the whole passed through a loop in the iron leading in wire and secured, a piece of canvas is then wrapped round and fastened with string.

An iron frame with two wooden rollers fitted is then fixed in the flush-box, the cable is made to pass over one roller and under the other, the latter is so arranged that the cable enters the pipe with a clear lead and without being chafed against its edges.

After a few sections have been drawn in, the jointers follow, numbering the wires and making permanent joints.

Within the last five years nearly the whole of the underground wires in London have been relaid. The work has been effected with comparatively little or no interruption of the working circuit, and by less than is experienced from removals on railways or road lines.

The wires are tested periodically from the central station by means of a Wheatstone bridge and Thompson's galvanometer. To prevent stopping the circuits two wires (where available) are used between St. Martin's and the points to which the wires are to be tested, one joined to an instrument for speaking, and the other for substituting the working wire during the time it is being tested. The average insulation is about twelve megohms per mile.

The position of faults are determined by a loop test, and as a rule is very correct. It seldom happens that a joint is found defective, but generally something within the pipes, probably caused by lightning.

If this view is correct, it would be well to have means of fixing lightning protectors at the ends of each underground route.

A few years ago it was customary to cut or prick wires when one was wanted at a point where numbers had not been attached. This was a very dangerous practice, and frequently led to interruptions of working owing to the cuts or pricks not being made permanently good. At the present time, by means of a quantity current and a horizontal galvanometer, a wire can be found at any point of the London street work without any difficulty, by merely placing each wire over the galvanometer.

Elect News Aug 5. 75

Improvements in Grapnels for Raising Submarine Cables.—Walter Claude Johnson, civil engineer, 38, Old Broad Street, London. December 10, 1874.—No. 4253. The object of this invention is to cut the cable and to raise one end only. The shank is similar in form and size to that of a grapnel ordinarily used for recovering cables. At the base of the shank are formed strong deep tapering jaws, preferably two in number; in each of these jaws is placed a hinged clip capable of receiving the bight of the cable, the inner surfaces of which are roughened or grooved so as firmly to grip the interposed cable. A bolt of lead or other suitable material is placed under the clip so as to keep it in the best position for receiving the cable, and a steel spring keeps the sides of the clip pressed firmly against the cheeks of tapering jaws. The prongs are made wide at their base so as to guide the cable into the before mentioned clip. Near one end of this clip is situated a V knife, which is similar in construction to that in ordinary cutting grapnels.

Subterranean Telegraph Line.—M. Holtzmann.—A line of this kind, forty miles in length, is laid in the neighbourhood of Amsterdam. A cast-iron trough is placed in the bottom of a trench, and filled with an insulating mixture, liquid pitch still in the warm state. The gutta-percha covered wire is then put in the liquid, the trough is closed with a lid, and the trench filled up.

THE HOOPER CABLE SHIP.—This vessel has been built specially for the Hooper Company, and is fitted with three iron cable tanks built into, and with the ship, thus rendering them an element of strength instead of a source of weakness, as instances on record. The largest tank is 53 feet in diameter, and each one is 30 feet deep. The *Hooper* is propelled by a double-bladed screw, driven by compound surface-condensing engines, the high-pressure cylinder being 52 inches in diameter, with a 48-inch stroke, and the low pressure cylinder 92 inches in diameter, the piston rods being carried up through the cylinder covers. The engines are placed well aft, and take steam from four circular multitubular boilers. Besides the ordinary screw propeller, the *Hooper* is fitted with a transverse screw, placed a short distance inwards from the propelling screw along the keel, and driven by a pair of powerful engines in a deck house. The object of this screw is for manœuvring the vessel whilst laying the cable when it is expedient to remain on one spot. The arrangement has been tried, and proves to be quite satisfactory; when the main engines are stopped, and the transverse screw started, the vessel can either be kept stationary or hovering about one particular point. The vessel is not without appliances for saving labour, both on deck and below; water is laid on throughout the vessel, and her saloon and cabin accommodation is excellent. She was built by Messrs. C. Mitchell and Co., of Newcastle-on-Tyne, in seven months. The engines were built by Messrs. Thomas Clark and Co., and the paying-out and picking-up apparatus are by the Vulcan Foundry Company. The *Hooper* has a speed of 8½ knots, although when laying the cable she will not be required to run at more than 5 knots per hour. When loaded with 5000 tons, and drawing 23 feet of water, she displaces 1500 tons of water. She will take 1200 tons of coal on board for an average trip. She carries many thousand fathoms of grappling rope, composed of seven strands, each consisting of seven wires, separately covered with Manilla yarn, likewise grapnels, buoys, and necessary adjuncts for grappling or buoying the cable, should such a contingency as a break occur. A fine wire apparatus for sounding has been devised by Mr. Hooper, and answer well for great depths. In paying-out, the cable is led from each tank in succession to a series of five grooved pulleys, which it passes over and under alternately, each pulley being fitted with a strap break. The cable then passes round a drum 6 feet in diameter, fitted with a powerful strap break, and thence over the paying-out wheel, 4 feet in diameter, and placed at the stern, a dynamometer being used to indicate continuously the strain on the cable. The picking-up apparatus is situated near the bows of the vessel, and is worked by a powerful double-cylinder engine carried on the same framing as the winding apparatus. The electrician's room is placed below deck between the main and after tanks, whilst there is a small house on the deck for jointing and similar operations. The batteries are upon Sir William Thomson's improved principle, the bluestone liquor being contained in long-necked bulbs, whose openings are loosely stopped with tow, and the necks inserted in the charged cells, the exudation of the liquor being by capillary action. These are stated to be both economic and satisfactory. The apparatus is so arranged that signals can be transmitted through the cable, and insulation readings taken at the same time. Signalling apparatus is fitted throughout the vessel to facilitate instant communication from one department to another.

Revue Hebdomadaire de Chimie, Vol. iv., No. 22.

New Method of Firing Mines, Dynamite, &c.—By M. Toselli.—The principle by which M. Toselli proposes to supersede the present method of firing mines by electricity, is the transmission of pressure in a liquid. The inventor employs a metallic tube of about one centimetre in diameter laid from the firing station to the mine. At one of its extremities, the tube is in connection with a very feeble pressure pump, and at the other is fitted with a piston which is attached to the trigger of a pistol or to a fuse. By the slight motion caused by pressure of the water, the trigger is moved, and sets fire to the powder or other explosive material.

Electrician Sept-14.78

THE BLOWING UP OF HELL GATE AT NEW YORK.—*La Nature*, in the issue of Sept. 7, gives details of the use of electricity in this gigantic operation. The electricity for the purpose of igniting the dynamite cartridges, containing 50,000 kilogrammes of dynamite, was obtained from a bichromate of potash battery, consisting of forty-eight cells, each containing ten elements. The zincs and carbons were arranged so that they could be raised from or lowered into the exciting fluid at pleasure. To obtain the exciting fluid, 80 kilogrammes of bichromate of potash were dissolved in 650 litres of water and 130 litres of strong sulphuric acid. The cells were thus grouped:—Seven batteries of 44 elements each, four of 43 elements, and twelve of 40 elements, and each battery was expected to explode eight groups of 20 cartridges. The cartridges were connected by conducting wires to little cups filled with mercury. Above these cups a metallic plate, connected with the battery and held by a rope, was placed, so that when it fell contact was immediately made. The rope held a cartridge, connected through a key with a cell. At a certain time the carbons and zincs were lowered into the exciting fluid. The daughter of General Newton pressed the key, the cartridge connected with the rope exploded, the rope was broken, and the contact plate descended, making the mine contact, and the dynamite exploded. The success, as we all know, was complete, and we only refer to the affair to show the part played by electricity.

Elect News Sept-23.75

165,535. *Underground Telegraph Lines.* David Brooks, Philadelphia, Pa. Filed June 2, 1875.—1. An underground telegraph wire or cable clothed with absorbent material, covered with insulating substance, and contained within a pipe, in combination with a liquid insulating medium maintained under pressure within the said pipe, all substantially as set forth. 2. An underground telegraph wire or cable surrounded by pipes arranged in sections, each section being bent upward at the ends, as set forth, and terminating in a box or receptacle, B, for the purpose specified.

SEA SOUNDING.—Sir William Thomson has recently patented an ingenious method of sounding, which can be put in practice without reducing a ship's speed. The pianoforte wire sounding apparatus of the same inventor was a great improvement on the old fashioned lead-line, and has done good service in the American navy and on cable-ships, notably the s.s. *Hooper* and *Faraday*. By the wire-sounding apparatus a great deal of time is saved, owing to the small amount of friction of the sea water on the wire in sinking and in hauling in, as compared with the friction on the rough hemp surface of the lead-line. Owing to the speedy execution of a wire sounding, it was also possible in shallow water to take a series of flying soundings from a ship without slackening her speed as she approached the coast,—a great advantage to a mail steamer in thick weather. One objection to flying soundings by the wire exclusively, lay in having to take the great slant of wire paid out as a measure from which to deduce the depth, since owing to the ship's motion, it was impossible for the wire to drop vertically down to the bottom. The new invention of Sir William Thomson measures the depth independently of the wire paid out, which, however, may serve as a check on the other result. The pressure of the sea-water at the depth to which the lead sinks is made the means of registering the depth, in the following way. A glass tube closed at one end and open at the other, is lined inside with a colouring matter such as aniline blue, red prussiate of potash, or, better still, chromate of silver, which will be acted upon chemically, and discoloured by sea water. This tube, suitably guarded in a brass guard-tube against accidents, is lowered with the lead-line into the sea. The sea water, forcing its way into the tube by the open end, compresses the air-column therein, and mounts up the tube to a height corresponding to the pressure, and discolours the lining of the tube in its passage. The discolouration in the tube marks the height to which the sea-water has penetrated, and this becomes a measure of the water pressure, and consequently, by employing a suitable scale, of the depth in fathoms to which the lead was sunk. A chromate of silver lining of the tube is turned from orange yellow to white by the action of the sea-water. Instead of discolouring the lining by sea-water alone, the sea-water itself may be tinctured by a dye as it enters the tube; or it can be arranged by proper valves simply to trap the water in the tube, and retain it there until it can be brought to the surface and its height read off. The indicator tube and lead-line are used in conjunction with the pianoforte-wire apparatus. Recent trials of this new apparatus on board H.M.S. *Minotaur* have proved highly satisfactory.

plied, that some action should be taken and the pirates hunted down.

Since the 13th of February all the offices of the Spanish provinces of Gerona, Barcelona, Lerida, Tarragona, Castellon, and Teruel, which had been closed through the Civil War, have been re-opened for work. The international service has also been re-established by the Franco-Spanish frontier of Perpignan Junquières. This will, no doubt, affect the receipts on the Barcelona and Marseilles cable belonging to the Direct Spanish Company, but to what extent remains to be seen. The cable has been well-worked, and has had an excellent and well-deserved traffic, and may yet be able to compete with the French and Spanish land lines. On the other hand, the receipts on the Santander line to England will, as soon as commerce is re-established at Bilbao in its old state, increase considerably.

In our last we mentioned that the Direct Spanish cable had been repaired in the s.s. *International*, Capt. Hayward. The work has been carried out by Mr. Benest, who was second Engineer on the laying of this cable, and has had considerable experience in cable work. The work was near a dangerous coast with a heavy Atlantic swell rolling in on it, and as another cable, belonging to the Spanish Government, between Santander and Bilbao runs parallel with and close to the cable repaired, the successful repair of the cable, without injury to the Government cable, does great credit to those engaged in the work at this time of the year.

The cable between Calais and Denmark has been for some weeks broken down, and the steamer *Caroline* is working at the repairs. Why this cable was ever laid seems difficult to imagine, as it runs parallel to the coast of countries in which numerous inland telegraph lines between France and Denmark exist. It must cross, at right angles, some eight or ten telegraph cables between this country and the continent, and all crossings of cables are objectionable, as if the crossed cables have to be raised, it would be difficult to do so without breaking or cutting one of the cables.

The Australian and New Zealand cable has been laid successfully by the Telegraph Construction Company. This cable is of a novel pattern. Instead of an outer sheathing of iron wires touching one another, as in the pattern of the Mediterranean deep sea cables, or of wires covered each separately with hemp, as in the Atlantic cables, we have alternately a wire and a hemp strand. This makes the cable cheaper at first cost, but we doubt whether it will be cheaper in the end to the company for whom it has been laid.

The steamship *Edinburgh*, which laid a portion of the cable, has been purchased by the "Eastern Extension and Australian Company" for £15,000 from the Telegraph Construction Company, and will remain out as a permanent cable repairing ship. Permanent repairing ships are a step in the right direction, but we cannot say that in this case the buying Company have been judicious in the selection of a ship, notwithstanding that they have a ship of 2,315 gross tonnage for £15,000. She is not a spar deck ship, and yet for a cable ship, a spar deck, so as to give plenty of room below, is almost a necessity. If she is a sound ship with compound engines and fully fitted with tanks and machinery she should be worth at least three times the price. The jump the company have made from the miserable little *Agnes*, the ship they have hitherto had for their former lines, to a ship of 2,315 tons is extreme, and there is something suspiciously small about the amount of money paid for the *Edinburgh*, which savours of getting rid of a broken down old horse for a song. We believe the selection of this ship as a repairing ship was in no way due to the engineers of the Extension Company. Most likely it was a matter arranged entirely between the Chairman and Managing Directors of the Companies with the advice, no doubt, of some "intelligent boatswain

The Direct United States Company's Torbay, New Hampshire, section is repaired. The cable was found cut with a hatchet. It is nothing new to find cables in shallow seas cut to clear nets and anchors; but the depth of one hundred fathoms, in which this was found cut, is greater, we believe, than any previous experience has shown.

The *Faraday* is to be kept out for the present as a repairing ship until the Company get one of their own. It is most strange that it should only now be dawning on the directors of the Direct United States Company that a repairing ship is necessary. With their opportunity of profiting from the experience of other companies they might have built the most perfect repairing ship by this time, and saved a considerable sum of money.

The Brazilian Submarine is another company without a repairing ship. These two companies are the only large companies without repairing ships. We suppose both companies will keep putting off the evil day until, under pressure of a break-down, in a hurry they buy some imperfectly arranged old tub, with the machinery crowded, not enough tanks and separate coiling spaces, and no room for the extra crew and stores.

A permanent repairing ship or cable ship should have plenty of room between decks for crew, stores, and men to work at splices, &c., and have

The Telegraph Construction Company have commenced the manufacture of the cable for duplicating the Eastern Company's system between Suez and Bombay.

Tel Jour Apr 15 76

In our last we mentioned that the Committee appointed by the Admiralty, the Board of Trade, and the Trinity House, to consider the rules of the road at sea, had issued their report. Amongst the alterations proposed, is the following relating to telegraph cable ships:—"Art. 5. The following ships, viz.—A steamship laying or picking up a telegraph cable; a steamship which, in consequence of accident to her machinery or steering gear, or for any other reasons, is not under command, shall, by day, carry in a vertical line, one over the other, not less than three feet apart, in front of but not lower than her foremast head, three black balls or shapes, each two feet in diameter; and shall at night carry, in place of her masthead light, three red lights in globular lanterns, each not less than 10 inches in diameter, in a vertical line, one over the other, not less than three feet apart. These shapes and lights are to be taken by approaching ships as signals that the ship using them is not under command, and cannot therefore get out of the way. The above ships, when not making way through the water, shall not carry the side lights, but when making way shall carry them."

These proposed regulations have been submitted through the Foreign Office to all the countries which have adopted the existing International Regulations, and of course must be endorsed by them before they can become law.

It was certainly time that something was done as regards the lights of telegraph ships. In 1862 Sir S. Canning called the attention of the Admiralty to the subject, and in August of that year the Admiralty issued an order compelling all ships laying cables to carry two red lights at night in addition to the side lights and masthead lights, and two black balls at the foremast head by day. The order was not sufficiently published, and the late Shipping Act ignoring it altogether, it was no longer legal to carry these lights.

The present proposal does not seem a good one, as the same lights are to be used by steamers that are broken down as by a telegraph steamer. The consequence will be that every telegraph steamer will be taken for a broken down steamer, and consequently ships will bear down on them to see if they require assistance. It was greatly to prevent this that special lights for telegraph ships were required, as ships often come ranging alongside a telegraph ship at night, thinking she is a disabled ship and adrift like themselves, to ask if they want assistance; whereas the telegraph ship is perhaps moored by the cable she is picking up, and thus there is danger of the other ship drifting on to her. It will also be seen that if this proposal is made law every ship will have to carry on board three red lights and three balls so as to have them ready in case she breaks down.

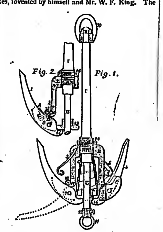
Proceedings of Societies.

THE SOCIETY OF TELEGRAPH ENGINEERS.

At the ordinary general meeting of this Society, Nov. 16th, Mr. ANDREW JAMIESON, C.E., read a Paper on "Cable Grappling and Cable Lifting." After reviewing the various kinds of accidents which produce faults in submarine cables, and classifying them into faults by

abrasion, anchors, teredo, deterioration of core, lightning, Mr. Jamieson described the process of grappling and lifting cables. He pointed out that the present mode of stoppering a cable when it has been raised up to the bows on the grapnel is unsatisfactory: a man having to be lowered to cut it with a saw: and also suggested that improvements might be made in lighting mark buoys. At present these buoys are lit by a lamp attached to the pole of the buoy by a boat's crew, a clumsy, and in rough weather, a dangerous mode. Captain Collison's buoy, which is lit by gas compressed to 10 atmospheres within the buoy itself, has been recently tried during gales at sea; and had kept alight for twenty-two days and nights; the light being visible four miles by the glass, and two by the naked eye. This buoy, Mr. Jamieson thought, was worthy of trial. It may be mentioned that in the discussion which followed the paper, Mr. W. H. Preece related that he had seen a buoy off Sandy Hook which compressed air as it rose and sank on the swell, and gave out a powerful whistle. Mr. Jamieson then came to the subject of grapnels, and after describing the ordinary grapnel, the centipede and Lambert grapnels, he gave a detailed account of the grapnel with hinged flukes, invented by himself and Mr. W. F. King. The



special advantage of this grapnel is that in moving over the bottom should the prongs or flukes encounter a rock, they will not be broken off as in the case of the ordinary and centipede grapnels, but will bend backward until they relieve themselves from the obstruction, when the grapnel is freed. On the other hand, should the cable be caught it will fall into the hollow between the stem and shorter flukes, where it will be retained. The figure represents a section through this form of grapnel, where 1 is the stem and 10 is the shackle; 2 is a hollow cast iron box, containing a stout spiral spring 6; 4, 4, are the moveable flukes, long and pointed, turning round pivots 7, 7; 8, 8 are the shorter flukes which retain the cable 18, when it is caught, although the longer flukes 4, 4, may be bent back. The flukes 4, 4,

ing, and, if need be, undermining the cable. From a note that each wire should be the care of a rope line well saturated with boiled tar, and that the lines should finally be made into a rope treated in the same manner, one can form some idea of the nature of the cable which was contemplated. The scheme of connecting France and England expanded in the following year, 1841, into one for connecting Portpatrick and Donaghadee, and laying a cable across Portsmouth harbour from Portsmouth to Gosport. The Channel telegraph still, however, retained the uppermost position in his mind, and with this object in view a preliminary experiment was carried out in September, 1844, with some insulated wires submerged in Swansea Bay. The communication was preserved with the Mumble-head Lighthouse, and it is interesting to note that the old lighthouse-keeper, who had been an assistant in some department to Sir William Snow Harris, exhibited the keenest possible anxiety as to the result of what was going on, and rendered all the assistance in his power by reading the signals and communicating with those who were out in the boat. A letter from Wheatstone to Captain Beaufort, R.N., of the Admiralty, written in September, 1845, shows that the Channel project was still prominent in his mind, and from the pointed inquiries which it contains give evidences of the shrewdness and far-sightedness of the man. In these inquiry is made as to the action of sea-water upon lead, from which it would appear that he had some idea of employing this metal as the protective covering. As early as 1845 it would appear that Sir Charles Wheatstone intended to employ guttapercha in connection with his cable, although in what capacity is not clear. In that year he endeavoured to obtain some, but failed, owing to the fact that the last parcel had been bought by Mr. Hancock, of Charing-cross, and

credit of Mr. Newall that what was used by him at the birth, so to speak, of submarine telegraphy, should be taken up and all but universally employed even now, with all the accumulated experience of later times. With reference to the historical portion of the subject, the Spezzia-Corsica cable was the first one in deep water, laid by Mr. Brett along with Mr. Thompson, one of Mr. Newall's head assistants. In some places the depth was as much as 500 fathoms, and as the cable weighed about 7 tons to the mile, extra precautions had to be taken with the break power. Two ordinary drum breaks, each with double straps and five turns round each drum, were employed and answered the purpose. The same machinery failed in the following year with a 6-wire cable. After two starts from the land about eighty miles of cable were brought back, whilst sixty miles were picked up afterwards by Mr. Liddell and Mr. Webb in the *Elba*. This was the first heavy cable picked up from deep water.

In the case of the Bona-Cagliari cable mention is made of water-tight tanks having been used. That is hardly the case; they were iron tanks, but never intended to be water-tight. There is one historical fact in connection with this cable which deserves to be mentioned. It was the first cable on which a dynamometer was made use of. Its employment was first recommended by Dr. Werner Siemens, and adopted by Mr. Newall. Mr. Webb then entered into a minute description of this dynamometer, and the various improvements which have since been effected in it.

Mr. Webb confessed himself unable to answer the question put in the paper as to whether the formulæ of Messrs. Longridge and Brooks are correct or not. Considering, however, the number of cables whose submergence has been based upon the calculations of Messrs. Longridge and Brooks,

THE TELEPHONE AND SUBMARINE CABLES.—It is sometimes necessary to grapple and lift a faulty ocean telegraphic cable, and if it lies in the water along with other cables of similar exterior make, it has hitherto been impossible to decide, without cutting it apart, on the identity of the grappled portion. To avoid the evil of having to cut and splice the cable unnecessarily, it is now suggested to employ the telephone on an auxiliary parallel wire in which the induction may be sufficiently strong to enable the electricians in charge to read the signals which may be sent into the cable, and so identify it.

Proceedings of Societies.

THE SOCIETY OF TELEGRAPH ENGINEERS.

(Concluded from page 106.)

The secretary then proceeded to read a very interesting communication which had been received from Mr. Sabine with reference to Sir Charles Wheatstone's early ideas of a submarine telegraph. This was accompanied by carefully executed drawings, to illustrate the type of cable to be employed and the mode of submergence to be adopted between France and England. From the letters in Mr. Sabine's possession it is found that as early as 1837 this was a subject in which Sir Charles Wheatstone was taking the greatest interest. It was when under examination before a Select Committee of the House of Commons some years later—the 6th of February, 1840—that he gave the reply which has now become historical, as to the practicability of establishing electrical communication by means of a cable between Dover and Calais. Towards the close of 1840 the drawings, which were exhibited, were executed. One of these shows very clearly the method of insulating and manufacturing the cable, as well as the means to be adopted for shipping it; the other shows the route to be taken and the methods of laying, join-

NOTES RELATING TO ELECTRIC FUZES.*

By F. A. ABEL, F.R.S., Treas. C.S.

The earliest practical application of electricity to the explosion of submerged charges of gunpowder was made by Sir Charles Pasley, who, in the course of operations which he was carrying on for removing the wreck of the *Royal George* at Spithead, consulted the late Professor Daniell and Sir Charles Wheatstone, at King's College, on the subject, the result being the employment by him of a form of Daniell's Battery for the purpose of heating to redness a platinum wire surrounded by gunpowder.

In 1856 the subject of the application of electricity to the explosion of gunpowder was referred for experimental investigation to the Ordnance Select Committee, of which Colonel Bainbridge, R.E., Sir Charles Wheatstone, and I were then members. The investigations had reference to the further development of the application of high tension currents, as obtained with electro-magnetic induction coils and frictional machines (including Armstrong's hydro-electric machine), to the explosion of mines, and especially to the utilisation of magneto-electric induction apparatus in the same direction. The production of a highly sensitive and otherwise efficient fuze for employment with such instruments, as well as with other high tension apparatus, was made the subject of special investigation by me, in which I received most valuable assistance from Mr. E. O. Brown. After applying gun-cotton and various other highly sensitive compounds and preparations as priming (or vehicles for ignition) of such fuzes, the ultimate result was the production of the high tension phosphide of copper fuze, through the agency of which even small voltaic piles and so-called galvanic chains, as well as the simple forms of magneto-electric machines manufactured for medical purposes, became available for the explosion of mines. A very efficient magneto-electric exploding machine was also devised, by Sir C. Wheatstone, by means of which a large number of those fuzes could be exploded in divided circuit with such rapidity as to have the practical effect of simultaneous explosions in operations on *land*, and which served as the foundation for the construction of other instruments of the same class. Although the highly sensitive character of the phosphide of copper fuze has rendered it very valuable and superior to other fuzes of similar nature as a means of exploding mines and groups of mines, both land and submarine, its very sensitiveness became an obstacle to its employment with confidence in *submarine* mines. I was therefore recently led to devise a modification of the high tension fuze, specially designed for use in submarine mines, and which, while possessing the requisite sensitiveness to ignition, has been proved by ample experiments to sustain with absolute safety the transmission of any test-currents to which it may be necessary or desirable to submit them.

This fuze dispensed with the necessity for employing cumbrous and troublesome batteries, and rendered the success of exploding operations independent of distance and of good metallic connections. These high tension fuzes met with varying success. One chief objection arose from their deterioration whenever they became moist, and to which accident they were very liable. A very substantial objection to their use in submarine mines was, however, the liability to considerable alterations in conductivity by being frequently, or for long periods, submitted to even feeble test-currents, and the possibility of its accidental ignition by passing through them such comparatively powerful test- or signal-currents as it may be found necessary to

employ in conjunction with an efficient system of submarine mines. The new tension fuze, specially devised by me for use in submarine mines, is, as already stated, quite free from the latter defect, and, though its conductivity is by no means unaffected by the long-continued transmission of test-currents through it, the changes to which it is liable in this respect have been found, so far as present experience goes, not to affect its efficiency. Owing to the great liability which high tension fuzes have of exploding accidentally from induced currents a lightning discharge will probably decide whether it is desirable to replace them with low tension or wire fuzes.

The highly permanent character of platinum, combined with the comparatively great resistance which it opposes to the passage of an electric current, has led to its being almost exclusively used until quite recently as the material for the construction of the bridge or the source of heat in low tension fuzes. The wire of this material hitherto used in the production of fuzes for military purposes has varied somewhat in diameter, and the resistance offered by it is not very high. Its average diameter is about 0·003", and its weight 1·65 grains per yard; its resistance is equal to about 31 ohms per yard, so that the length of the wire which has generally been introduced into the construction of a fuze has offered a resistance of about 0·2 ohm. Several very full experiments were made to ascertain how far the sensitiveness of low tension fuzes could be increased by employing thinner wires than 0·003" inch, and it was found that the conductivity of such *fine* platinum wires as are employed in the construction of electric fuzes is but slightly affected by physical differences in the metal from which they are produced, and that the considerable variations observed in the electric resistances of commercial samples of fine wires are ascribable to variations in chemical quality or degree of purity of the metal.

In the course of these experiments it was brought to my notice by Lieut. Bucknill, R.E., that Mr. Farmer, of the United States, has recently devoted much attention to the improvement of [illegible] for the explosion of mines, and had applied German silver wire to the construction of low tension fuzes with very promising results; also that Commander J. Fisher, R.N., had entertained the idea of using an alloy of about 33 parts of platinum with 66 of silver, adopted by Matthiessen for the reproduction of the standard of electrical resistance. With the view of ascertaining whether wires of either of these alloys presented decided advantages over fine platinum wire, I obtained some from Messrs. Johnson and Matthey, which were submitted to experiments. The conclusions arrived at are as follows:—

1. Both the German silver and the platinum-silver alloy are greatly superior to platinum in regard to the resistance opposed to the passage of a current, and the heat consequently developed in giving lengths of wires of a particular diameter.

2. German silver is, in its turn, superior in this respect to the platinum-silver alloy, as is especially apparent in the finest wires. This superiority, though very marked in considerable lengths of wires of the same diameter, is, however, only trifling in short lengths; the comparatively ready fusibility of the platinum-silver wire contributes, with other physical peculiarities of the two alloys, to reduce the fine German silver wire to about a level with it, and sometimes even to a somewhat lower level, as regards the thermal effects produced. Some slight influence in this direction may perhaps also have been exerted in these particular experiments, by the greater cooling power exerted, by the brass supports between which the wires were fixed, upon the German silver wire of comparatively low specific gravity.

In selecting a wire for the construction of low tension fuzes, its power to resist corrosion when in intimate contact with gunpowder or other substances employed as the igniting medium in such fuzes, especially if some moisture should be accidentally absorbed by them, possesses an important bearing upon its permanent efficiency. In Matthiessen's report on the application of platinum-silver wire to the preparation of standard resistance coils it is stated not to oxidise by exposure to air; it has, however, been observed to do so gradually, to the extent of becoming tarnished, and as, with extremely fine wires, a very superficial oxidation might appreciably affect the resistances of fuzes constructed with them, it was thought desirable to ascertain by actual experiment of a somewhat severe nature the power of such wires to resist corrosion in comparison with German silver wire. It was, of course, unnecessary to experiment with platinum wire in this direction. Wires of the two alloys, about 8 inches long, were enclosed in glass tubes, and each wire was surrounded closely by gunpowder and gun-cotton in the ordinary air-dry condition; one of each being also simply enclosed in air for purposes of comparison. In addition, a length of about 2 inches of each kind of wire was buried in wet gunpowder, the extremities being allowed to protrude sufficiently for testing purposes. Slight fluctuations were exhibited in two or three instances in the resistance-measurements of the fine and comparatively light German silver wire in the foregoing observations, and are no doubt ascribable to the effects of fluctuations of temperature, which did not influence the readings obtained with the platinum-silver wire, its conductivity being less affected by changes of temperature than that of any alloy experimented upon by Matthiessen. In all three experiments with the German silver wires enclosed in tubes there were indications of very slight superficial oxidation, as demonstrated by the permanent, though small, increase in the resistance of these wires, which, in the case of its exposure to contact with gun-cotton, continued very gradually up to the forty-first day, when it f[illegible]eory. The resistance of the platinum-silver w[illegible] in glass tubes remained constant throughout.

The exposure of the wires to contact with *wet* gunpowder has afforded very marked evidence of the greater liability of the German silver wire to corrosion; at the same time it must be borne in mind that this test far exceeds in severity any conditions under which fuzes constructed with wire bridges would be likely to be preserved in actual practice. It will be seen that the platinum-silver wire remained unaffected by this test for thirty-two days after the continuity of the German silver wire had been destroyed by corrosion. The great influence of the charcoal in the gunpowder in promoting corrosion in its capacity as an electrolyte is interestingly demonstrated by the fact that the German silver wire remained buried for twenty-two days in wet saltpetre without undergoing great oxidation (which oxidation did not progress after that time), while the wire which was buried in wet gunpowder was destroyed by corrosion within six days.

The foregoing comparative experiments appear to warrant the conclusion that a wire consisting of the alloy, composed of about 66 parts of silver and 33 of platinum, is not only superior to a platinum wire of considerably smaller diameter as regards the resistance it offers to the passage of an electric current, but that it is also, practically, quite equal in this respect to a German silver wire of the same diameter, and is at the same time greatly superior to the latter in its power to resist corrosion.

In selecting the platinum-silver alloy as the material for the reproduction of standards of electrical re-

ON THE USE OF ELECTRO-MAGNETIC INDUCTION IN CABLE SIGNALLING.

By G. K. WINTER, F.R.A.S.
Telegraph Engineer, Madras Railway.

It will doubtless be remembered by most telegraph engineers that at the Brighton meeting of the British Association I brought forward a subject connected with signalling on submarine cables that I thought had not received the attention it deserved. This subject was the use of an induction coil at the receiving end of a cable, the current from the cable being made to pass through the primary wire, and the currents generated in the secondary wire being used for working the receiving instrument.

There was one point connected with my experiments, and passed over as a matter of course in my paper, which seems, nevertheless, to have been misunderstood. I refer to the fact that, having a primary wire adapted as to its length and resistance for making the most of the received current, you may fill up the space to be occupied by the secondary wire with wire of any diameter, so long as you use a galvanometer or other receiving instrument of an appropriate resistance; in other words, the secondary coil must be treated as a distinct rheomotor, and, therefore, according to a well-known law, the resistance of the galvanometer should be equal to that of the secondary coil.

The resistance of my primary wire was about 2500 units, and, as explained in my paper, the resistances of the secondary coil and the galvanometer were about 2·5 units each. It is manifest that signals even from a strong battery, if passed through, say, 20,000 units, would scarcely affect such a galvanometer; whereas, if the same signals were passed through the primary wire of the above-mentioned induction coil, this same galvanometer would be specially adapted to show the currents generated in the thick secondary wire. A galvanometer, however, of the same dimensions, wound with 2500 units of fine wire, would be far more strongly affected by the direct signals than the thick wire galvanometer would be, even when joined to the secondary wire of the induction coil.

The induction coil is not therefore able to increase the *obtainable* strength of signals, but, if wound as mine was, it is able to convert signals that require a high-resistance instrument to show them into others that are best shown by one with low resistance. There are some instruments that are essentially low-resistance instruments, and which cannot be modified in this respect as galvanometers can. Such instruments would, of course, be useless as direct receiving instruments from long circuits,

12 2 26

pole of a Daniell, the zinc of the Daniell is put in communication with β, the zinc of the Leclanché with α. The mercury moves out of the field. One turns the handle V till the mercury is brought back to zero; the manometer marks 270·5 m.m. of mercury. The electromotive force inscribed opposite this number in the table is $e = 0{\cdot}450$: hence 1 Leclanché = 1·450 Daniell.

ON THE THEORY OF CONSTRUCTION OF ELECTRIC FUSES.*

THE name *induction fuse*, given to fuses that are inflamed by a current from an induction apparatus, seems to have been applied prematurely. Considering that the currents produced, whether by discharges or by chemical actions, are ruled by the same laws, and vary only in their effects, we think the name of *tension fuse* may be much more rationally applied to fuses in which the platinum wire is replaced by a powder, whose conductivity may vary within certain limits, but which has a great resistance, capable of being overcome only by a current of high tension. To distinguish, however, the fuses, which are only inflamed by ordinary induction apparatus, and those which may be exploded either thus or by a battery current (40 to 150 piles in tension) we shall designate the former *induction fuses*, and the latter by the more general name of *tension fuses*. The induction fuse, of which that of Ebner is a type, is more easy of construction than these latter. For, in tension fuses, the conductivity, the compression (*tassement*), and the separation of the wires play a very important part, and if the conditions in these respects be not strictly fulfilled, the sensitiveness to inflammation decreases till the number of piles required puts such fuses beyond possibility of use.

In what follows we have assimilated the currents of static and dynamic electricity . . . We assume that the electric spark is only a particular case of the electricity of batteries of high tension.

We have observed that:—

I. With the same conducting powder, compression of it, and separation of the wires, the greater the section of wire the more is the galvanometer deflected. The cylinder of powder between the two sections of wires may be compared to a resistant conductor the conductivity of which increases with the section. We know that the conductivity of a wire is in direct ratio of its section.

We have determined empirically a constant diameter of wire, corresponding to a given sensitiveness of inflammation (with the same compression), verified by the deflection of the galvanometer. It may be easily conceived, that if we change the diameter of the wire, all other conditions remaining the same, the fuse will no longer have the same resistance, and to obtain the previous effect it will be necessary to alter the conductivity, and consequently the compression, with the result of presenting a greater or less number of conducting molecules to the action of the current.

II. If while diminishing the diameter of the wires we increase the compression so as to have the same deflection in the galvanometer, the fuse will be less sensitive to inflammation. In fact, suppose the powder cylinder between the sections of wires to represent a bundle of platinum wires, very fine, and therefore very resistant; to compress the powder is to bring close together the molecules forming it, or, in one comparison, to diminish the distance separating the platinum wires so as at length to form a single wire, of section equal to the sum of the partial sections. The resistance of the platinum wire to the current will not have changed, but as the heating of a wire traversed by an electric current varies in inverse proportion to the fourth power of the wire, it follows

* Abstract of portion of memoir by MM. Champion, Pellet, and Ortaler, in *Annales de Chimie et de Physique*.

The employment of tension fuses seems capable of obviating this inconvenience, the electric current necessary to their explosion having but an excessively weak tension proportionally to that of induction currents.

Riess has observed that a wire near that which allows the discharge to pass may retard the latter when it is a less good conductor. For the effect to be sensible the discharge wire must be wound in a spiral, as also the other, so that considerable lengths of the wires are in presence of each other. The two ends of the wire independent of the battery must also be joined so as to form a closed circuit. There is evidently an induction effect in the circuit the electricity of which reacts on that which passes in the discharge wire. The retardation is more pronounced the less conducting the induced wire.

It is evident, *a priori*, that we may prepare powders for induction, and tension fuses with a great quantity of substances, provided the mixture has a suitable conducting power. In this respect we believe we can rectify, *en passant*, some errors about certain bodies such as picrate of potash and nitro-glycerine.

Picrate of potash, even with chlorate of potash added, which much increases its facility of explosion, does not undergo any alteration in presence of ozone contained in the air; and they are mistaken who have supposed accidents, through explosion of the picrate, to have been produced by this cause; besides, no experimental fact can confirm this opinion.

As to pure and perfectly neutral nitro-glycerine, its fixity cannot be doubted since the labours of Nobel. This engineer has kept nitro-glycerine for more than ten years without observing any alteration, and our personal experiments on nitro-glycerine subjected to various temperatures fully confirm this fact. Certain spontaneous alterations of dynamite, sometimes remarked, have arisen from an incomplete neutralisation of the nitro-glycerine in consequence of defective manufacture.

SEVERAL foreign naval Powers are directing their attention to the practicability of establishing telegraph stations in mid-ocean, by which messages can be sent from any part of the sea along the line of the cable to the terminal points on shore, and *vice versa*, so that communication with ironclads, war steamers, and other vessels when out at sea, may be established. The invention for carrying out this scheme consists of a hollow sectional column with a base plate attached by ball and socket joint, which column is lowered into the water, and anchored rigidly to the ground. The branch cable is coupled to the main cable, and carried along the column to the surface of the water, to be there connected with instruments on board the vessels. By this invention it is proposed to control naval and strategical movements, whilst a ship in distress could communicate her exact position, the nature of her disasters, and thus procure assistance.

"Bridge" which bears his name. The object of the first-named instrument, we need hardly say, is to measure the current strength by the interposition of a wire which produces a known resistance; then, by varying the length of this wire by a definite amount, causing an equality in the galvanometric effect produced by any two currents, which may thus separately be compared, and the relative strength of one to the other thereby estimated. Under various forms this instrument still remains indispensable in the cabinet of the physicist.

But it is by "Wheatstone's bridge" that the subject of our memoir is, perhaps, most widely and gratefully remembered by physicists generally. The object of this instrument is too well known by every electrician to render it needful for us to describe it, further than to say it is essentially a differential instrument depending on the law of derived circuits, which Wheatstone was the first to apply to electrical measurement. Upon the same law he also describes, in the paper to which we have referred, the now universally-used "shunt," and shows how a delicate galvanometer can thus be employed to measure any current strength, giving, too, the necessary formula to be used when the "reducing wire"—as he terms it—is introduced. But our space is more than exhausted, though we have by no means exhausted the benefits Wheatstone has conferred to both pure and applied science.

It only remains for us to notice the personal loss this Journal has sustained by the death of Sir Charles Wheatstone. When the first number of the ELECTRICAL NEWS appeared, Sir Charles expressed to its present editor the liveliest interest in its future prosperity, and had, moreover, several communications with us respecting the means for increasing its usefulness and securing its ultimate success. Not only did he promise his invaluable aid, but even in the midst of feeble health he collected a number of hitherto unpublished notes, and it was arranged that a short-hand writer should—by taking down his thoughts—save him the trouble of writing. Unfortunately for ourselves, and we may add for Science also, Death laid its hand upon him ere his kind intentions could be carried out. It is to be hoped that the world will not lose the benefit of his unpublished papers, for we believe it is no secret that he had obtained latterly some new results which he esteemed of great value, and upon which he had promised us an early communication.

As we have regarded Sir Charles Wheatstone only from a scientific standpoint, leaving others to speak of him in his kindly home life, we cannot do better than conclude this hasty and imperfect notice in the words which Faraday uttered, nearly twenty years ago, as the lesson to be drawn from the career of one who did perhaps more than any single individual to increase the material and intellectual prosperity of mankind. Faraday says:—

"Wheatstone's life is an argument in favour of a large public recognition of scientific education, because in Wheatstone we find a man both of science and practice, and his career is a strong illustration of the effects which a general scientific education may be expected to produce. . . . Such an education teaches us to be *neglectful* of nothing; not to despise the small beginnings, for they precede of necessity all great things in the knowledge of Science, either pure or applied. It teaches a continual comparison of *small* and *great*, and that under differences almost approaching the infinite; thus the mind becomes comprehensive. It teaches us to deduce *principles* carefully, to hold them firmly, or to suspend the judgment; to discover and obey *law*, and by it to be bold in applying to the greatest what we know of the smallest. It teaches us first, by tuition and books, to learn that which is already known to others, and then by the light and methods of Science to learn for ourselves and for others,—so making a fruitful return to man in the future for that which we have obtained from man in the past."*

Such faithful words cannot be too often pressed upon the attention of the nation.

SIR WILLIAM THOMSON'S REPORT TO MESSRS. SIEMENS BROTHERS ON TESTS OF DIRECT UNITED STATES CABLE,

TAKEN AT BALLINSKELLIGS BAY STATION, SEPTEMBER 16 AND 17, 1875.

ON Wednesday evening, September 15th, I arrived at Waterville, and proceeded thence to the cable station at Ballinskelligs Bay. There your electrician, Mr. Ebel, met me, and showed me the instruments which he was ready to put at my disposal for the tests; and Mr. Gavey, the Company's superintendent, obligingly lent me a number of additional condensers which I desired for measuring the electrostatic capacity of the line. Having made preliminary arrangements, and learned that, by orders from London, the line was to be at my disposal from 7 till 10 next morning, I returned to Waterville for the night, appointing to meet Mr. Ebel at the station in the morning at 7 o'clock.

About 8 a.m. on the 16th, after some preliminary trials of the instruments in connection with the cable, which showed strong earth-currents, I commenced testing for insulation with a battery of 20 cells, having its two poles constantly joined through a resistance of 20,000 Siemens units, but found so great disturbance by the earth-currents that it was impossible to

* Faraday, Lecture on Wheatstone's Electric Telegraph in relation to Science; Royal Institution, January 11, 1858.

Electrical News, August 5, 1875.

SIR WILLIAM THOMSON'S METHOD OF DEEP-SEA SOUNDING BY PIANOFORTE WIRE.

On the 22nd of April, 1874, Sir William Thomson delivered a lecture before the Society of Telegraph Engineers, on his new method of deep-sea sounding by means of pianoforte wire. In that admirable lecture Sir William showed that the great merit of wires compared with rope is the smallness of the area and the smoothness of the surface which the wire presents, as compared with the greatness of the surface and its roughness when rope is used with a comparable degree of strength. Pianoforte wire, of the Birmingham gauge No. 22 has been found most suitable: it weighs about 14½ lbs. to the nautical mile, and bears from 230 to 240 lbs. pull without breaking. Messrs. Johnson produced a length of 3 miles, in one piece of crucible steel, capable of bearing a strain of about 230 lbs. One of the greatest difficulties to be overcome was the splicing of the wire. Experiment showed that a splice of 2 feet long was sufficient, but 3 feet may be safer. The two pieces of wire to be spliced are laid together, and held between finger and thumb at the middle of the portions thus overlapping. Then the free foot and a half of wire on one side is bent close along the other in a long spiral, with a lay of about one turn per inch, and the same is done for the free foot and a half on the other side. The wire has been previously coated with marine glue, just to increase a little the surface friction. The wires are found to cohere perfectly when splices are made in that way, all that is necessary to make the splice permanent being to cover the ends over for about an inch with a serving of twine just to keep the ends firm down.

The sounding apparatus as it is now finished and sent out by Mr. White, of Glasgow, and as it has been used by the screw-steamer *Faraday* on the Direct United States Cable Expedition, is represented in the accompanying figure, for which, with the description, we are indebted to the editor of *Engineering*. It consists of a large light drum, A, of galvanised sheet iron, on which the wire is carefully coiled. The free end of this wire terminates in a stout galvanised iron ring, *b*, and to this ring the sinker *c* is attached by a hemp line, *d*, several fathoms long. The interposition of the line between the wire and sinker prevents the wire from reaching the bottom, and the ring is heavy enough to keep the wire tight: thus kinking of the wire is avoided. The circumference of the drum is 1 fathom, and an indicator *e* is fixed to the axle to indicate the number of revolutions of the drum. A slight correction, due to the thickness of wire on the drum, has therefore only to be applied to the indicated number of turns in order to give the amount of wire paid out, or depth of the sounding in fathoms.

In order to stop the drum immediately on the sinker reaching the bottom, the brake F F is employed: it consists of a friction-cord attached at one end to the framework of the apparatus, and passing over a secondary groove on the circumference of the drum A, the other end being weighted at *g*. By means of this brake the increased pull on the wire due to the amount of it paid out is to be more than counteracted, so that the drum will revolve by a pull on the wire due to something less than the weight of the sinker; for, in this case, when the sinker is supported by the bottom there will be a friction on the drum bringing it to rest. The weights *g* have, therefore, to be applied gradually, as the wire runs out. The rule adopted in practice is to apply resistance always exceeding by 10 lbs. the weight of the wire out. Then, the sinker being 34 lbs., we have 24 lbs. weight left for the moving force: that is found amply sufficient to give a very rapid descent—a descent so rapid that in the course of half an hour or fifty minutes the bottom will be reached at a depth of 2000 or 3000 fathoms. The person in charge watches a counter (the indicator *e*), and for every 250 fathoms (that is, every 250 turns of the wheel) he adds such weight to

hung on a couple of fathoms of cord, but a greater length would have been better. I believe that 5 fathoms ought to have been used. Then the wheel was simply let go with a resistance of about 8 lbs., or, perhaps, an actual resistance of not more than 6 lbs. on the circumference of the wheel. When the ship was running at the rate of 4½ knots an hour, the cable was paying out at the rate of 6 knots; and after, perhaps, 150 fathoms had run out—in some cases 175 fathoms—suddenly the wheel would get so much slower that it almost stopped. In half a turn it was obvious that there was a difference. The moment that difference was perceived, the man standing by laid hold of the rim of the wheel and stopped it. Thus we achieved flying soundings in depths of 150 fathoms with the ship going at the rate of 6 miles; and we obtained information of the greatest possible value with reference to the depth of the water and the course to be followed by the cable. I think this is of such great importance that I never would like to go to lay a cable without an apparatus for flying soundings to be regularly practised, say every two hours at the least."

THE GOVERNMENT TELEGRAPHS.

A REPORT, dated July 17, 1875, of the Committee appointed by the Treasury to investigate the causes of the increased cost of the Telegraph Service since the acquisition of the telegraphs by the State, has just been presented to Parliament. It bears the names of Alfred Austin, H. Weaver, and W. O. Anderson.

The points which received the attention of the Committee were:—

(1). The causes of the very serious discrepancies between the estimates of telegraph expenditure, year after year, and the actual outlay.

(2). The general expenses of the service as compared with those of the telegraph companies.

(*a*). As to the conduct of the business, and the staff employed for the transmission of messages.

(*b*). As to the cost of maintenance and extension.

(3). The extent to which offices and services are maintained which are not required by public convenience, and are not paying their expenses.

The following is an abstract of the result of the inquiries into these several points:—

Comparative statement of the expenditure on Telegraph Services, as compared with the grants for the different years since the transfer of the telegraphs to the Post Office, taken from the appropriation accounts rendered by that department to the Comptroller and Auditor-General—

Year.	Grant.	Expenditure.	Surplus.	Deficit.
	£	£ s. d.	£ s. d.	£ s. d.
(3 months) 1869-70 ..	90,000	62,273 11 5½	27,726 8 6½	—
1870-71 ..	360,000	409,493 8 8	—	49,493 8 8
1871-72 ..	420,000	551,521 11 10	—	131,521 11 10
1872-73 ..	669,970	871,915 17 8	—	201,935 17 8
1873-74 ..	858,000	967,917 18 8	—	109,917 18 8

The Post Office asked for a grant of £90,000 for the three months ending March 31, 1870, but the transfer of the telegraphs to the Government having been postponed to January 29, 1870, the grant taken for the expenses of the entire quarter exceeded by £27,726 8s. 6½d. the expenditure of the months of February and March.

It appears from a Parliamentary return of August, 1870, only six months after the date of the transfer, that there were at that time employed in the telegraph branch no less than 4913 clerks, &c., instead of 1528 as proposed, and 3116 messengers, instead of 1283; so that the staff of the telegraph branch as compared with that of the companies was more than doubled. This fact alone will

UNDERGROUND TELEGRAPH WIRES.

A Pioneer Line Between the Fire Department and Police Headquarters.

Underground telegraph wires are being laid from the Fire Department Headquarters on Mercer street up to Houston street, thence to Mulberry street and to Police Headquarters. The wires are being laid by the United States Underground Telegraph Company by arrangement with the Fire and Police Departments. Sixty telegraph wires and six telephone wires run from the Fire Department building. Seventy-two wires are being laid under ground, so that there will be six extra wires. At the corner of Houston street thirty-four wires will be connected with the above-ground system of the Fire Department. Thirty-two wires will be carried underground to the corner of Houston street and Broadway, where they will be connected with the above-ground wires of the department. Six wires will be laid the whole distance between the Fire Department Headquarters and the Police Headquarters on Mulberry street. The entire length is between 1,500 and 1,600 feet, and it will be the largest underground line yet laid in this country.

In laying the wires an excavation is made to the depth of about two feet. A wooden trough is laid down, and in this the wires are placed, immersed in a composition which, it is claimed, perfectly insulates them. This composition is a mixture of powdered glass, paraffine wax, resin, and linseed oil. It is melted and poured in hot, and when it solidifies it is a tough, hard composition, impervious to moisture, and unaffected by changes of temperature. It will bend without breaking, and cannot be broken by the shifting of the earth or settling of the street bed. The wooden trough is simply a mould, which may rot away without affecting the efficiency of the cable. Instead of the ordinary galvanized iron wires of above-ground telegraphy, the wires used in the underground system are of copper, with two coverings of cotton fabric, soaked in paraffine wax. In placing the wires, a half-inch layer of the insulating composition is first put in the trench; then eight wires are put down, three-eighths of an inch apart; then comes another half inch of the composition and eight more wires, and so on until the seventy-two are enclosed in a rectangular cable 5¼ inches wide and 3½ inches thick.

Mr. A. T. Woodward, who is in charge of the work, speaks enthusiastically of the qualities of this species of underground cable, and thinks that it will eventually supersede all above-ground wires, and that it will secure the department against storms or accidents.

He said: "Before beginning this work an experimental line was laid in Prospect Park, Brooklyn. It was a quarter of a mile long, with four wires giving a circuit of a mile. It was laid down last fall, in a shallow trench. The ground was frozen hard all winter, and was like mush in the spring, but the working of the wires was at no time affected. During the great winter storms, when there was a loss of four-fifths of battery power in the ordinary lines, there was no loss of power at all in the underground line."

Talking of underground cable laying in general, Mr. Woodward said: "The difficulty always has been to maintain the insulation of the wires. In London the underground system has been adopted, and the method there employed is to lay the wires in a packing of gutta percha or vulcanized rubber enclosed by iron or earthen pipes. The cables are laid in sections of 400 yards each, with test boxes between each section so as to locate breaks. There is an underground line of this kind between London and Manchester, thirty-six miles, but the cost is between $7,000 and $8,000 a mile, and frequent renewals of sections are required. In Paris telegraph wires are laid underground by means of cables carried through the sewers. The sewers are so large and well ventilated that workmen can go in and out without trouble, but it is a plan that with such a sewer system as we have here could not be imitated. In Berlin, also, the telegraph wires are laid underground, but they are made like ocean cables, with costly gutta percha and rubber packing and covering, making the cost upward of $2 a foot. In this city the only underground wires are the Western Union [illegible] cables. These are laid in gutta percha, enclosed by iron piping. Experiments have been made in the use of paraffine oil inside iron pipes, but it has been found that the oil gradually oxidizes and loses its non-conductivity."

It is claimed for the underground wires now being laid that the cost is much less than any of the foreign systems, and that while it is greater than the ordinary above-ground wires, yet the system is much cheaper from its saving in cost of repairs and maintenance. The average life of the ordinary pole and line telegraph is eight years, and the cost of repairs and maintenance takes up one-fourth of the receipts. When the underground wires are properly laid it is claimed that the cost of maintenance is inconsiderable. Moreover, the workings of the wires will be unaffected by the storms which now sometimes destroy all telegraphic communication between cities for a time.

Ironmonger June 18 1881.

UNDERGROUND TELEGRAPH WIRES.

THE reply of Mr. Fawcett, Postmaster-General, to a question recently asked in the House of Commons by Sir Henry Tyler will be received with feelings of general satisfaction. This feeling will be especially notable in the metropolis, which has suffered more, even in proportion to its size, from the dangers of overhead wires than any of the large towns and cities of the country. With the extension and development of the telegraphic and telephonic systems the plan of suspending the wires overhead has become an intolerable nuisance, a source of great danger, and a decided eyesore. Some of the streets of the City are literally cobwebbed with wires crossed and recrossed in every conceivable direction, so that in high winds or during extremely low temperatures the danger to pedestrians and others is a very grave matter. Mr. Fawcett now explains that the Post Office authorities are reducing the extent of the overhead wires in favour of the underground plan, and that they are endeavouring to diminish the mileage under the old system as rapidly as possible. The efforts hitherto made have been largely successful, seeing that in 1877 there were 1720 miles within a radius of four miles of the General Post Office, whereas now the mileage is only 500, and the underground wires have increased from 3,350 miles to 1,308 miles in the same period. This is satisfactory so far as it goes, but the extension of the telephonic wires is a matter which requires prompt and vigorous action on the part of those concerned. It has been proved to demonstration in Germany, New York, and elsewhere that underground wires can be successfully insulated and maintained, so that there need be no obstacle whatever in the universal adoption of the system—the carrying out of which would not only be a gain to the public, but would be an especial benefit to our tube manufacturers, founders, and others engaged in various branches of some of the industries represented by this journal.

Wm Radde's Patent

The Manufacturer and Builder. June '76 127

the value of this important improvement, which speaks for itself, and, as seen from the above, is very fast gaining in favor with the building trade.

Underground Telegraph Lines.

The continually increasing objectionable features of the common clumsy and unsightly manner of carrying telegraph wires above ground on high poles, is calling attention more and more to the investigation of the best system of underground conductors for the subtle agent, electricity, at present one of the most indispensable servants which the ingenuity of man has succeeded in training for the use and benefit of modern society.

Every observing person is satisfied of the defects of the present system in use in this country, and we need only mention some of them, without wasting any space, to demonstrate the reality of these defects. The most striking are: 1st. Unsightliness of the poles and wires in cities, especially when many wires pass along the fronts of beautiful buildings. 2d. Danger to the public by the falling of poles and wires during a storm. 3d. The impediment they offer to the firemen in buildings situated behind many wires stretched in front.

These are the objections from the side of the public; but the telegraph companies who use the wires, also have objections, chief among which is the danger to which the conductors are exposed to damage, and thus lose their usefulness.

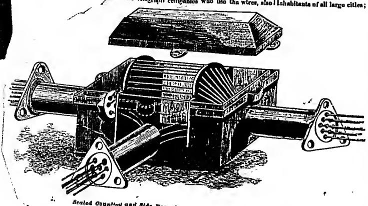
4th. Constant care and repair are required, as prostration by storm may interrupt the current by breakage or entanglement of the wires. 5th. Mischief can more easily cut a wire or throw down a pole than damage a well made underground conductor. 6th. Rain and moist weather cause such losses of electricity as to make an increase of battery power necessary, and consequently an increase of expense. 7th. Thunder-storms and auroras may throw or induce so much electricity into atmospheric wires as to seriously impede the transmission of messages. 8th. It is easier to intercept a message by tapping an atmospheric wire than to do it with a subterranean wire.

These are only some objections, to which others may be added, and which do not exist in underground conductors. The only question is to make the latter so as to secure perfect isolation, to have them out of the way of harm, and still within reach so as to be at any time accessible for repairs and additions.

This difficult problem has been imperfectly solved in the European systems of underground telegraphs, and notwithstanding this, they are being more and more extensively substituted for the highly objectionable air lines. What then must be the future of a most perfect system of American invention, which is not only entirely free from all the above objections of the air lines, but also from the objections of the European underground lines? Being perfectly reliable under all circumstances, either for news messages or as a guard to life and property, and being composed entirely of inorganic substances, it is not subject to decay, and needs no repairs, like the gutta-percha covered wires and similar contrivances. It consists of a multiplicity of very small glass tubes, (from 3 to 18 and upwards) put in an iron pipe. The naked copper wires are drawn through these glass tubes, which are held in the required position by paraffin wax.

For lateral connections, as well as convenience in laying the wires down, traps are used, into which the pipe is screwed, the wires passing over non-conducting bridges, thus allowing any wire to be taken out and replaced if desired, without interfering with the working of the others. The pipes are connected by a coupling, which, after being bolted together, is completely sealed with paraffin wax, the traps being closed and sealed in like manner. Such a trap is represented in the adjoined engraving, with the cover removed and the sides open to expose the interior.

It is clear that the advantages of wires so protected are that it does away with the telegraph poles, and thereby satisfies the demands of the authorities and inhabitants of all large cities; it saves the great cost of the constant care and repair of the wires suspended from the poles, and reduces the cost of transmitting messages. By this system we have no crossing of wires, no difficulty from atmospheric changes, no cutting of wires in cases of riot or for the purpose of defrauding, no imperiling of life and property by the breaking down of poles and wires by snow-storms or fires, (causing interruption of telegraphic communication,) but a perfectly reliable telegraphic connection under all circumstances. The advantage of the ingenious invention described, will be more evident still when we examine the underground system now in use in Europe. This is laid mostly in cables, coated with an organic material, which soon disintegrates, while all the wires become useless in case any of them need replacing. In this system any of the wires can be taken out and replaced without interfering with the others, each wire being exactly in the same position on one end of a line as it is on the other end.



Sealed Coupling and Side Branch of Underground Telegraph Line.

The system of an underground telegraph has been thoroughly tested, and has the indorsement of the best electricians in this country and in Europe. It has been publicly discussed before the Polytechnic Club of the American Institute of New York, and has been on exhibition and in operation at the fair of the American Institute in this city, receiving the diploma in 1875.

Mr. Wm. Radde, of 548 Pearl street, New York, has the patent, where further information may be obtained. Samples of the pipe and a working model of this system are on exhibition at the Centennial Exhibition at Philadelphia, in Machinery Hall, Siding 6, Class 555, Location B, 5, 20. This underground telegraph system has been laid between the Commissioners' and Finance buildings (72 wires) connecting these buildings, and registering all admissions to the Centennial Grounds by being connected with the turn-stiles at the entrance.

occur in any other cables, and the fact that the high reward offered for the detection of any malicious cable breakers has failed to bring forth even an accusation, must be taken as strong evidence in favour of the correctness of our opinions. But, moreover, Mr M. I. Gaines, Superintendent of the Anglo-American Telegraph Company at Duxbury, in a letter to the *Boston Herald*, states that the Anglo-American cable from Duxbury to St. Pierre, laid in 1869, has been broken regularly every year since it was laid except in 1874, and that in 1875 it was broken three times during the year. He also states that this cable has been broken, curiously enough, on the 26th, 27th, and 29th days of May in different years, and that all the breakages with one exception have been within the space of fifty miles, while five of them have been within a space of ten miles. The owners and captains of the fishing-boats that broke the cable, have on several occasions been kind enough to report all the details of the accidents, which he proceeds to give as a conclusive demonstration that the breaking of the Direct Cable has been accidental, and not from malicious intentions or motives. Mr. Gaines gives the following example of the way the cables are broken. On the 4th of May, 1873, the cable was broken 66 miles from Duxbury by the fishing schooner, J. W. Bradley, of Bucksport, Massachusetts. The facts in this case were that the day before the cable was caught it came on to blow severely. The schooner broke adrift just before night, and they had out about 180 fathoms of cable. In the morning when the schooner hove up they supposed the anchor had caught bottom. After about 80 fathoms had been hove in they found their anchor was hung, and continued to heave for six hours, getting only a turn on the windlass as the schooner pitched down as the sea rose and fell. At last they saw they had the cable, and while waiting to devise the best way to clear their anchor the cable parted. "This," Mr. Gaines says, "is the way it is done. It is always the same story with variations only of time and place. The skipper hooks the cable, heaves up his chain as far as he is able, putting a severe strain on the telegraph cable, and then swings to it, a heavy sea strikes him, or a tremendous ground swell throws him upwards like a cork, and something has got to go smash. That something is generally the cable, being the weakest." This account is much more in accordance with general experience than the opinion given by Sir W. Thomson and Mr. Bramwell in their report, viz., that "If a fishing vessel having hooked the cable accidentally brought it up to the surface and endeavoured to get the anchor on board, the cable could not be broken in the process," and we may safely assume that the Direct Company's cable has been broken in the same way that the Anglo-American Company's cables have been.

The Direct Company's cable has now happily had a long respite from these accidents, and has been working well, and it has been the turn of the Anglo-American Company's system to be interrupted, yet we do not find the Anglo-American Company insisting on any malicious breakage of their cables. Their Brest-St. Pierre cable—commonly called the French Atlantic—broke down on April 26, and the repairing ship Minia, which happened to be in the Thames, was despatched in a few days to the fault about 200 miles from Brest, a locality where the cable broke down in 1873. Unfortunately on May the 4th, before the repairs could be completed, the last of the cables between Placentia Bay, St. Pierre, and Cape Breton, broke down, thus completely stopping the communication between Newfoundland and New York. One of these was quickly repaired by a steamer hired for the purpose. But it was thought advisable to get another of the Placentia cables repaired, and the Minia was ordered to leave the French Atlantic cable and proceed on May the 18th to Newfoundland to effect this, which she has done. For the repair of the French Atlantic, the s.s. Hibernia, which has just returned from laying the Australia and New Zealand cable has been hired from the Telegraph Construction Company by the Anglo-American Company. She is fully fitted with machinery and tackle, and Mr. J. Laws, the experienced electrician, and Mr. London, one of the engineers of the Telegraph Construction Company, are entrusted with the work. The Hibernia left the Thames on the 18th, and we shall, therefore, no doubt soon hear of the repair of the French Atlantic cable.

With regard to the 1865 cable, which has been broken down since March, 1873, we believe no steps are to be taken this year as regards its repair. Indeed, it seems very probable that now it never will be repaired, for if the Anglo-American Company having now two repairing ships in their employ, cannot spare a ship to work at it, although it has been broken for three years, there will most probably be no better chance at any future date.

The coast cables, on the other side, seem to be the most troublesome to both companies, and in any future Atlantic cable it will be desirable to study very carefully the routes to be taken, and if no better than the present can be found, the cables must be of a heavier pattern, for the interruptions are too frequent for a single repairing ship to keep pace with. At the present moment Atlantic telegraphy is employing three repairing ships. Should an amalgamation take place between the companies, some of this expense might possibly be saved, for whilst the Anglo-American Company were in want of a repairing ship on the other side of the Atlantic, the Faraday was on that side and unemployed. In any case, the Anglo-American Company's system of cables from Placentia Bay to St. Pierre and Cape Breton, is not proportionate to safety from complete interruptions to their sections across the Atlantic, for whilst complete interruption has only occurred on the whole of the deep-sea cables once, and that when there were only two cables, and never since there have been more than two, the failure of the short cables has twice caused complete interruption on their system, and has not unfrequently caused them to be dependent on only one cable to carry on the messages from St. Pierre and Newfoundland, although these places were fed by four cables from Europe.

NEW ZEALAND TELEGRAPH.—Telegraphic communication with New Zealand has been successfully established. The New South Wales end of the cable was laid at Botany Bay on Saturday, February 5th, and the *Hibernia* and *Edinburgh*, the two steamers engaged in laying the submarine cable, then proceeded on their voyage to New Zealand. The work was performed in a very expeditious and successful manner, the whole work being completed within a fortnight. The New Zealand end of the cable was landed at Nelson. On the completion of the work congratulatory messages passed between the Governor of New Zealand and the Governors of the various Australian Colonies. The charge for sending messages from Melbourne to New Zealand is 10s. 6d. for ten words, and 1s. for every additional word.

SAN FRANCISCO CABLE.—The United States corvette *Tuscarora* has arrived at Brisbane. She has been taking deep-sea soundings from San Francisco to Honolulu, and thence to Moreton Bay in view of the proposed construction of a submarine cable between San Francisco and Queensland. It is understood that the route is considered particularly favourable for the projected cable. After coaling and provisioning, the *Tuscarora* will proceed via Sydney to Auckland, and run a line of soundings thence to Kandavu, to ascertain the feasibility of cable connection.

A telegraphic cable is about to be laid down between Havre and Honfleur. It will join the Normandy coast at a point between Honfleur and Trouville. The steamer Ampere, destined for the operation, can immerse a cable with a velocity of three miles an hour. A cable has just been laid between Marseilles and Bona in Algiers. Aug 77

Eng TELEGRAPHS. Feb. 76

We are glad to see that the Anglo-American Company are beginning to see that their cables cannot last for ever, and have, therefore, determined to create a renewal fund at the rate of 100,000*l.* per annum. They also state that the attempt to repair the 1865 cable in their repairing ship the *Minia* will be made this year. This at once shows that they now think it possible to repair the cable with a ship of only 2000 tons, although they were persuaded that no ship but the Great Eastern could repair it, and thus expended 70,000*l.* three years ago. It seems astonishing that the years 1874 and 1875 should be allowed to pass without any attempt at repairs. The chances of success must be much diminished by the time that has elapsed since the cable first failed three years ago.

The Direct Spanish Cable was announced as broken on the 4th instant. The rupture is near Santander. This cable originally started from Bilbao, but during the siege of that town in 1874 the cable was diverted by the company to Santander. It was cut at sea about 7 miles off Bilbao, and a cable run from Santander along the coast to the place where the line was cut and there spliced on to the part leading to England. This portion of cable, about 30 miles, lying parallel to the coast in shallow water, and being only deep-sea cable, except a short portion of shore end near Santander, will be always liable to interruptions, this being the second since it was laid. For cables to last when running parallel to the coast, they require to be of very substantial proportions. Of course this deviation could only be considered as a kind of temporary work. As soon as the Carlist War is over we presume the cable will again be diverted to Bilbao by splicing up the original cable. Possibly the deviation cable may also be run into Bilbao by an additional length of cable, so as to give the company a line between Santander and Bilbao, but as it is only a deep-sea line it would not last very long. The Spanish Government last year had cables laid by Mr. Hurley from Santander to Bilbao and from thence to St. Sebastian. Thus there are three shore ends at present in Bilbao Bay. If the deviation cable is carried in also this will make a fourth. The bay is very narrow and there is much anchorage to keep clear of, while it is necessary to lead all the cables on one side of the bay. It seems very doubtful whether all these shore ends can be kept clear of one another, and if one ever has to be repaired the chances are that the others might be hooked or damaged when dredging. It is decided bad engineering to take four shore ends into so narrow a span. The Spanish Government are responsible for taking the second and third cables there. We notice that a Mr. Steenackers has been appointed by the Brazilian Government to put all the telegraphs in Brazil in order. Surely this cannot be the gentleman of that name who, as Minister of Telegraphs under the Government of National Defence in France, received a commission of 8000*l.*—according to evidence given in the case of Aspinall *versus* the India-Rubber, Gutta-Percha, and Telegraph Works Company—on the price of 88,000*l.* for a telegraph cable to be laid from Bordeaux to Dunkerque for war purposes during the war, thus drawing on the finances of his country at a time when his countrymen were bleeding by thousands in the field. At the trial one of the counsel called it a *douceur.* "Bribe" said Baron Bramwell. "It is a good Anglo-Saxon word." The last we heard of this worthy gentleman was that he had left his country and retired to Lisbon, and it appears almost improbable that it is the same person of whom we hear from Brazil. We cannot conceive what Brazil could want with his services. Dr. Capanema, the present director, is an able and scientific gentleman, and all the aid we should think he requires would be a few engineers practically acquainted with modern work and not addicted to receiving heavy commissions.

We learn by telegram that the Turkish Government has forbidden the transmission of telegrams in cipher over their telegraph lines.—*Railway News.*

In a circular issued by the directors of the Direct United States Cable Company, they mention the following particulars concerning their traffic during the interruption on the Anglo-American system:— June 1876

"The rush of traffic over the "Direct" cable practically lasted from the 4th to the 9th of May, inclusive, during which time 83,141 words were actually transmitted over the line. On the two heaviest days—viz., the 5th and the 9th of May—14,402 words and 15,906 words were sent over the line during each day, making an average speed for the whole of the 24 hours of 10 and 11 words respectively (the highest speed reached was 18 words per minute).

This speed, it must be borne in mind, was attained over the longest section of the system, viz., the main cable of 2,500 nautical miles.

On the shortest section of the line the speed was, of course, very much higher.

Considering the fact that the work usually performed by five cables was done during this time by one, it is a matter for congratulation that the maximum delay reached no more than about 15 hours, and that only at the time of the greatest pressure."

With regard to the interruptions in the Anglo-American system between Newfoundland and America, *The Telegrapher* of May 6th states: "This week all the other cables of the Anglo-American Telegraph Company are interrupted between the Island of St. Pierre and Placentia Bay, Newfoundland, which cuts off all communication between the cables which land at Heart's Content, N. F., and the connections this side, entirely suspending business.

"As the break is on the short section between Nova Scotia and Newfoundland, it will not probably take long to repair it. Unfortunately, the *Minia*, the regular repairing steamer of the Anglo-American Company, is at present on the other side of the ocean; but, another, a small boat, which has occasionally been engaged for repairing purposes, will be chartered, if possible, for the emergency."

The Telegrapher of May 13th, says: "The cable from Placentia Bay to Heart's Content, Newfoundland, is broken, and two of the cables connecting St. Pierre and Sydney, and four connecting Sydney and Placentia have been broken during the last two weeks, and now only one of them is in operation."

A NEW CABLE.—We learn from Madrid that a royal decree has been published authorising the Minister of the Colonies to accept proposals for laying a submarine cable between Manilla and Hong Kong. Dec 78

[Journal of the Telegraph.]

THE PRESENT METHOD OF TELEGRAPHING THROUGH OCEAN CABLES.

The peculiar conditions which are met with in the transmission of electricity through long submarine lines render it necessary to employ apparatus and methods for telegraphic correspondence which differ very materially from those used on land lines. The general principle, however, is that of the single needle telegraph of Cooke. In order to avoid any possibility of injury to the insulating coating of the cable, it is an essential condition that none but very weak currents should be employed, and for this reason the ordinary receiving instruments, which for the most part depend upon the action of electro-magnets, and require currents of considerable force to actuate them, are not available. It would occupy too much space to refer in detail to all the reasons which render it necessary to employ on long cables like those which have been laid across the Atlantic Ocean between Europe and America, the sensitive reflecting galvanometer of Thomson, but it is proposed in this article to describe the arrangement of the apparatus at the stations by which the effects of the phenomenon of induction are overcome and the speed of signalling increased to the greatest practicable extent.

In Fig. 1 the manner in which the different parts of the apparatus are arranged at Valentia, Ireland, and Newfoundland, for operating the Atlantic cables, is shown in the form of the diagram. The condenser C consists of alternate sheets of tinfoil and paraffine paper, interleaved, and contains an aggregate inductive surface of 40,000 square feet. It occupies a space three feet long, two feet wide and five inches thick, and is inclosed in a box and surrounded on all sides by a thick body of paraffine. The switch *e r t* is a common three point switch, which serves to connect the cable K either with the transmitting keys T or the reflecting galvanometer G (which forms the receiving instrument) when sending or receiving. The double key T, in connection with the battery B, is arranged so that one key, *a*, sends a positive and the other, *b*, a negative current from the battery to line. W is a very large resistance, which connects the end of the cable K to the earth at the point where the former is attached to one side of the condenser C. The battery B usually consists of about five elements of the kind illustrated in Fig. 2.

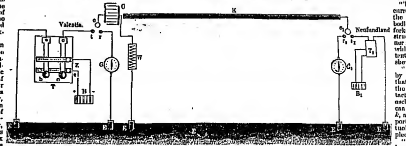

FIG. 1.—THE PRESENT MODE OF TELEGRAPHING THROUGH OCEAN CABLES.

If Valentia wishes to transmit to Newfoundland, the operator shifts the connection at the switch at *e* from *r* to *t*. When the key *a* or *b* is depressed, then one set of plates of the condenser C is charged either with positive or negative electricity, as the case may be. If, for example, the key *a* is depressed, then the + E of the battery flows by way of *c a t* and *e* to one set of plates of the condenser; hence the — E of the cable, in connection with the earth at Newfoundland, is attracted, and condensed on the other set of plates, which are connected with the cable, while the + E of the cable is at the same time repelled and driven towards Newfoundland. In this way there arises in the cable a positive current from Valentia towards Newfoundland, passing at the latter station by way of *e'* and *r'* to the receiving instrument or galvanometer G', and thence to the earth, and by the deflection of the spot of light upon the scale produces a + indication. When the key *a* remains depressed but for a moment the flow of current through the cable is of short duration, for as soon as the key is released and touches the bar *z*, not only does the process of charging the condenser terminate, but its discharge as well as that of the cable itself immediately commences. The + E of one side of the condenser immediately begins to flow to earth by way of *e t a z* and *b*. This sets free the — E of the opposite side of the condenser, which flows off through the cable to Newfoundland. On the other hand, the + E still present in the cable, not having had time to escape to the earth at Newfoundland through the galvanometer G', flows in the direction of Valentia, where the cable is in connection with the earth through the very large resistance W. Therefore there will be, under these circumstances, two simultaneous currents in the cable of about equal strength, but of opposite polarity or direction, which reciprocally neutralize each other, and thus destroy the inductive action which the original positive current had set up in the outer coating of the cable. By this means the cable becomes completely discharged.

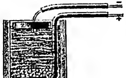

FIG. 2.

By making use of a similarly arranged condenser in Newfoundland, a communication may, in the same manner, be forwarded in the opposite direction; though it is stated that the Atlantic Telegraph Company, in order to avoid Varley's patent, have not adopted the system devised by him, but operate the cable by the use of a single condenser C at Valentia, which answers for transmission in both directions. With a single condenser the signals are sent from Newfoundland in the following manner:

When a key is depressed at T', then the electricity, for example the + E, flows directly into the cable K, and arriving at Valentia, flows almost entirely into the side of the condenser C, which is attached to the cable, the resistance of W being so great that comparatively little of it goes to the earth. The accumulation of + E in one side of the condenser causes a like quantity of + E to be driven out of the opposite side of the condenser, passing through *e r* and G to the earth, giving a + signal upon the galvanometer. When the depressed key at Newfoundland is again released, putting the cable at that place to earth, then the + E stored up in the condenser flows back into the cable, producing a + current towards Newfoundland, which lasts for a certain time, partly because the discharge of the condenser is not instantaneous, and partly on account of the inductive action set up by the original current. At the same time the — E from the opposite side of the condenser flows through the galvanometer G to the earth, and produces a — signal. In consequence, however, of the great distance between the condenser and the battery, and the short time during which the keys are depressed in transmitting signals, the potential of the charge of the condenser is only about one per cent of that of the battery itself. For this reason the — E which flows from the opposite side of the condenser through the galvanometer to the earth produces a very weak pulsation, which has but little effect upon the needle other than to make it return more quickly to its position of rest, and does not in any way interfere with the regular signals.

It will be seen, therefore, that in this method of working the cable by means of a single condenser, the depression of the positive key at either terminal station produces exactly the same result—namely, the deflection of the needle towards the + side, and in like manner the depression of the negative key at either station gives a — signal. The combination of these two signs, so as to form letters and words, according to the Morse code, is precisely the same as in the single needle instruments, which the cable instruments in fact are.

The insertion of the shunt W, having a very high resistance, which may be considered almost infinitely large in comparison with that of the conductor of the cable, gives rise to only a small loss of current, while it keeps the cable in constant connection with the earth—a result in many respects advantageous. The advantages gained by working with condensers instead of a direct current from the battery, may be briefly stated as follows: The direct current can only affect the galvanometer by first charging the entire cable, while the flow of electricity from the condenser through the galvanometer to the earth commences at the same instant as the charging. When, therefore, the key is depressed, the indication upon the galvanometer follows much more quickly with the condenser than it would with a direct battery current. In addition to this, the period of deflection only lasts during the time of charging, for the moment the potential of the condenser equals that of the pole of the charging battery, the needle immediately returns to zero, even if the key remains depressed. The practical advantage of the method of working with condensers is so great, that a speed of from twelve to eighteen words per minute is reached on the cables between Valentia and Newfoundland.

LA COUR'S "MUSICAL" TELEGRAPH.

HAVING already given a description of the telephone, or musical telegraph, invented by Elisha Gray, of Chicago, Ill. (SUPPLEMENT No. 8), our readers may be interested in the somewhat similar system invented by M. Paul La Cour, the sub-director of the Copenhagen Meteorological Institution. The following is from the *Telegraphic Journal*: "In the electric telegraph, up to the present time, but two simple signals have been employed, and these have been formed either by currents in opposite directions, or by the prolongation, to a greater or lesser extent, of the duration of the current. The system which I devised on the 10th May last enables, however, a large number of simple signals to be made with a single conducting wire.

"When a vibrating body, at each of its vibrations, is made to close and open an electric circuit, the pulsations of the current will, of course, be isochronous with the vibrations of the sonorous body; and when such currents are, by means of electro-magnets, made to act upon a second sonorous body vibrating in unison with the first, the second body will vibrate, whilst another similar body giving a different sound will remain silent.

"The first experiment was successfully made on the 5th June, 1874, but it was feared that the vibrations might cease to be perceptible after traversing a long distance. I therefore made an experiment upon a telegraph line 900 kilometres in length (from Copenhagen to Fredericia and back), and, even with a rather weak current, the pulsations were easily perceptible. This experiment was made during the night of the 14th-15th November in the same year.

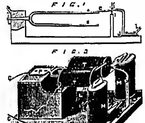
"To produce the intermittent currents and receive them at the further end, the sonorous bodies employed were tuning-forks. The apparatus is constructed in the following manner: The key or instrument which produces the intermittent current in the line is shown in Fig. 1.

"SS is a tuning-fork fixed by the shank in such a way that at each oscillation one of the prongs touches the contact, *c*, during a portion of the oscillation. The contact, *c*, can be adjusted by the screw, *k*, and, together with its support, is insulated from the tuning-fork by the insulating piece, J.

"When the shank of the tuning-fork is connected to one of the poles of a voltaic battery whose other pole is to earth, and when the contact piece is connected with the telegraph line and thence to earth, a blow given to one of the prongs of the fork will cause an intermittent current to be sent into the line, the pulsation of the current being in unison with those of the fork.

"It follows that, by keeping the fork in vibration, the same result will be obtained whenever the circuit is closed at any given point. It always follows that, by employing a contact upon the inside of the fork with a special battery for the same, the line can be charged with a succession of currents in opposite directions.

"The receiving apparatus is shown in Fig. 2, where P is a tuning-fork of soft iron, giving the same sound as that of the key. The prongs are inserted lengthwise in the coils, T T, which are surrounded by silk-covered copper wire; the prongs are so arranged as to vibrate freely within the centres of the coils. The intermittent current, on arriving at the station, passes through these two coils, and thence into the wire of an electro-magnet, M M, which is arranged so that its poles are placed in front of the opposed poles produced in the fork. It is evident that the current, in magnetizing the electro-magnet and the fork, produces an attraction which will open the prongs of the latter, but directly the current d, consequently, the attraction ceases to operate, the prongs will return to their position of equilibrium, and so on.



LA COUR'S MUSICAL TELEGRAPH.

If then the pulsations of the current are in unison with those of the fork, the vibrations of the latter will soon attain a sufficient extent for one of the prongs, n, to touch the contact piece, D, closing the circuit, C C, of a local battery, and thereby manifesting the arrival of the current in the usual way, either directly or by means of a relay.

"I can not as yet, I admit, state the time required to produce in the fork of the receiving apparatus vibrations of a certain extent; it is a function of various factors, but experiment shows that the time which elapses before the local circuit is closed is so small a fraction of a second as to be hardly perceptible, even when the current is very weak. In the hope that this

34

The average time which messages for India, via Teheran, by the Indo-European Telegraph Company, have occupied in transit during the month of April, has been, from Calcutta 32 minutes, Bombay 33 minutes, and other places in India 53 minutes.

The following, from the *Journal of the Telegraph* gives further information regarding the repair of the Havana and Key West 1869 cable in the s.s. *Professor Morse*. This is, we believe, the first repair executed by an American staff in a sea cable, and appears to do them great credit.

The party reached Havana on April 4th, and left on the 5th, in small boats, for Cojimar, where the cable lands. Tests located the fault at 1.3 knots from the shore. Attempts were at once made to raise the cable by underrunning with the small boats, but it was not until the afternoon of the 6th that the junction of the shore end with the intermediate was brought on board. The cable was cut at this joint owing to its unfavourable appearance, but as the tests showed the wire shoreward to be in perfect condition, it was rejointed. To facilitate the work it was here deemed advisable to procure a light schooner, which having been done on the 8th, underrunning was resumed, and at 1 p.m. a galvanometer on shore indicated that the fault had been brought up. This fact was signalled to the working party. The cable was cut and found to be perfect westward by tests with Key West. On the 9th connection was made with new cable on the *Morse*, and the steamer payed out to the point where the cut was made on the 7th, where the final splice was made. After completing the repairs the entire cable was tested for conductivity and insulation, and found to be in excellent condition, as shown by the following figures. Copper resistance per knot, 11.28 ohms. Dielectric resistance, after one minute's electrification, 339.8 megohms per knot.

REMARKABLE CABLE TELEGRAPHING.

A suit has been brought by the city of Philadelphia to enjoin the Western Union Telegraph Company from placing poles in Chestnut street, and to compel the company to run its wires underground. It was recently argued in the Court of Common Pleas No. 4, and affidavits from Mr. David Brooks and others showing the feasibility of operating subterranean lines were submitted. A question of fact arose as to whether underground wires in Europe had proved satisfactory. It was alleged on behalf of the defendant that such enterprises had almost invariably been abandoned, while on behalf of the city it was insisted that this was the method now in universal use in Great Britain and Continental Europe. The City Solicitor telegraphed to the post-office authorities in London early in the day, making inquiries in regard to the matter, and before noon a reply was received and read to the Court.

The following are the despatches referred to:

"PHILADELPHIA, March 6th, 1876. Charles T. Fleetwood, Chief Post Ofs. Telegraphs, Gen. Post Ofs. London, E.C.: Will you please inform me, by cable, whether the underground wires in London, referred to in your paper in the *Electrical Review* of January 15th, are in successful and perfect operation, and perform the same and as good service as if erected upon poles, and for how many years have they been performing such service satisfactorily?

"Are telegraph-poles in use in the principal streets of London or of any of the cities of Europe?

"In a case at this moment being argued between this city and the Western Union Telegraph Company, the latter contends that underground telegraphy has proved a failure in Europe. Is this so?

CHAS. H. T. COLLIS, City Solicitor."

LONDON, March 6th, 1876. Charles H. T. Collis, City Solicitor, Philadelphia: The underground wires in London, referred to in Mr. Fleetwood's recent paper, are in successful operation. It would not be possible to carry the same number of wires through London by overground work, nor would it be desirable, considering the atmosphere; but there are some overground wires which are carried over the housetops. There are no poles in the streets. All the important wires have been carried underground through London for the past twenty-five years.

"Pole and underground lines are in use in Continental cities.

"W. H. WINTER,

"Assistant Engineer in Chief, General Post Office, London, England."

The despatches were transmitted over the Atlantic and Pacific, and Direct Cable lines, and the time made was remarkable and the shortest ever made between Philadelphia and New-York. The despatch to London, which contained 126 words, was transmitted from Philadelphia to London, over land and cable lines, in twenty-three minutes; and the reply, which contained 108 words, was transmitted from London to Philadelphia in twenty-two minutes. The actual time in transmission of the despatch from London over the cable line was six minutes, the rest of the time being occupied in the transmission and repetitions over the land lines connecting with the cable.

In an underground telegraph system which is now in use at the Centennial Exhibition, connecting the Finance and Commissioners' Buildings, the naked copper wires are drawn through glass tubes, which are firmly held in position in the iron pipe by paraffine wax. For lateral connections, as well as convenience in laying, traps are used, into which the pipe is screwed, the wires passing over non-conducting bridges, thus allowing any wire to be taken out and replaced without interfering with the working of the others. The pipes are connected by a coupling which after being bolted together, is completely sealed; the traps being closed and sealed in like manner. By this system there is claimed to be no crossing of wires, no difficulty from atmospheric changes, no cutting of wires in cases of riot, no imperilling of life and property by the breaking down of poles and wires by snow storms or fires (causing interruption of telegraphic communication); but a perfectly reliable telegraphic connection under all circumstances.

July 76

— LA « DIRECT CABLE COMPANY » nous adresse une circulaire dont nous extrayons les renseignements suivants :

Il a été transmis par cette ligne, du 1 au 9 mai, 83,141 mots. Le 5 et le 9 mai, jour où le service a été le plus chargé, il a été expédié 11,402 et 15,906 mots, ce qui équivaut à une vitesse moyenne de 10 et 11 mots par minute. La plus grande vitesse obtenue a été de 18 mots par minute.

Il ne faut pas perdre de vue que cette vitesse a été atteinte sur la plus longue section du câble, soit 2,500 milles marins.

La vitesse, sur la plus courte section du câble, a été naturellement bien plus considérable.

Les recettes effectuées pendant les deux semaines, dans l'intervalle desquelles n'est produite l'interruption des câbles de la Compagnie anglo-américaine, ont dépassé 11,000 livres sterling, et, depuis lors, les recettes journalières sont bien plus élevées qu'elles ne l'étaient avant l'interruption.

June 76

The Peruvian exploring vessel *Chalaco* has been engaged in taking preliminary soundings between Chorrillos in Peru and Caldera in Chili, with the view of laying the submarine cable between these two points. The route examined was on a line starting from Chorrillos and passing within four miles of the Island of San Gallan, forming here a slight deviation towards the coast, and then running parallel to it for about twenty miles, about eight or ten miles off. The depth of the sea as far as San Gallan is not great, not exceeding a maximum of one hundred fathoms, the bottom all along being a mixture of mud and gravel. From thence the soundings begin increasing as far as the Morro of Chala, where a depth of 600 fathoms was noted. The submarine exploration, so far as it goes, proved that no difficulties would be met with in laying the proposed cable. 77

35

with Panama, on the Pacific coast, by a submarine cable, has, after protracted negotiations, been abandoned by mutual consent, it having been found impracticable to obtain the necessary landing rights at Panama, except on terms which the Company could not with advantage accept. The working agreement that existed between this Company and Mr. Henley, of North Woolwich, and which lapsed through the suspension of Mr. Henley, has been renewed with a Company formed for the purpose of carrying on his extensive works, on terms which, it is believed, will be advantageous to both parties."

CHINA.

SHORTLY after the establishment of the Torpedo College at Foochow, His Excellency Li Hung Chang, Viceroy of Cheli, First Guardian of the Emperor, &c., &c., sent an official request that Mr. J. A. Betts, the director of the college, should proceed to Tientsin with the whole of the torpedo apparatus just received from England, to carry out a series of experiments before His Excellency.

The *Chi-Ngan*, one of the Chinese gunboats, was ordered to convey Mr. Betts, and the stores, to the latter port, and during the month of October last a lengthened and very successful series of experiments in telegraphy and torpedo warfare were carried out in His Excellency's presence.

Telegraphic circuits were established, and a complete system of torpedo defence fully illustrated by the explosion of numerous torpedoes in the Pei-ho, near Tientsin. Further experiments with heavy charges were shown at the Taku Forts. His excellency lent his own steam launch for these trials, and expressed himself much pleased. The electro-contact torpedoes excited great interest and were much admired.

Mr. Betts exhibited the Royal Engineers' system of telegraphing by "Walker's Lime-light" on the city walls of Tientsin; this seemed to create a deal of astonishment among the Chinese, and although at a late hour of the night, and bitterly cold, caused an immense crowd to assemble.

Mr. Betts will return to Tientsin in the spring, when he will at once commence drawing up a system of torpedo defence for the Taku and Peh-tang Forts, which are also to be connected by a line of telegraphs.

M. Duchemin has found that nickel, deposited by electricity on the magnets of compasses, preserves them from oxidation. He deposited in this way a layer of nickel on several rings of one of his circular compasses, keeping two concentric circles free from the operation. This compass was put on board a vessel which went round the world. The rings covered with nickel preserved their polish, but the others were completely rusty. The magnetic power of the nickelized rings had been exerted with difficulty, no doubt on account of the magnetic property of the nickel. — *Comptes Rendus de l'Académie des Sciences*, Nov. 15, 1875.

Proceedings of Societies.

THE SOCIETY OF TELEGRAPH ENGINEERS.

Contributions to the Theory of Submerging and Testing Submarine Telegraphs.

By Dr. WERNER SIEMENS.

THE starting point of submarine telegraphy is to be found in the subterranean lines constructed in Prussia during the years 1847—1852. Before that time, it is true, attempts had been made to insulate wires with glass tubes, caoutchouc, &c., for use as underground lines. Experiments on a somewhat extensive scale by Jacobi* at St. Petersburg in the year 1842 deserve mention; but these attempts failed.

In the year 1846 the author suggested to the Prussian government the use of gutta-percha as insulating material, this gum having then recently become known in Europe. Its remarkable plasticity and insulating property appeared to render it very suitable to the purpose in question, but neither the experiments made at Berlin, nor those carried out simultaneously in England, were attended with satisfactory results; for the joints of the gutta-percha (which was rolled round the wire), gave way after a short time. At last, in the year 1847, the problem found its solution in a covering machine, constructed and used by the author and Mr. Halske, by means of which the gutta-percha, rendered plastic by heat, is pressed round the wire without any seaming.

During the subsequent years an extensive network of underground lines, insulated with gutta-percha pressed round the conducting wires, was somewhat too hastily and inconsiderately introduced in North Germany and Russia; although those lines were far from durable (particularly because the conducting wires, to save expense, were imbedded in the ground without external protection, and at too small a depth), they afforded opportunity of gaining practical knowledge for the construction and maintenance of such insulated conductors, and of studying their physical properties. But it was reserved for English enterprise to convert the knowledge and experience thus gained to practical account in a sphere where there was no competition with cheaper overground lines, that is to say, to submarine telegraphy.

As early as 1850, Mr. Brett laid a single gutta-percha-covered copper wire across the Channel between Dover and Calais. As might be expected, this became useless; but in 1851, Mr. Brett substituted a conducting wire insulated with gutta-percha, and protected externally by a sheathing of iron wires. This was the first practical submarine cable.

No great difficulties were encountered in laying these cables in the comparatively shallow waters of the Channel. But when later Mr. Brett endeavoured to lay such cables in seas of greater depth he failed, because the forces brought into play in laying deep sea cables were not yet recognised, and, consequently, the necessary precautions had not been taken. The laying of the first successful deep sea cable between Cagliari and Bona, in the year 1857, in which the author

SUBTERRANEAN TELEGRAPH JOINTS.—At a meeting of the Society of Telegraph Engineers held last week in the rooms of the Institution of Civil Engineers, Mr. C. V. Walker, F.R.S., in the chair, a paper, by Mr. Willoughby Smith, was read, on "The Formation of Joints in Gutta-percha Covered Wires for Subterranean and other Telegraph Lines." The author has given careful attention to the subject, and had at length succeeded in inventing what he had no doubt would prove a simple, cheap and efficient mode of dealing with one of the practical difficulties of subterranean telegraphy. The new joint is formed by removing the coatings from the two ends to be united and joining the cleaned wires by what is technically known as the "bell-hanger's twist"; no solder is necessary. The twist is then warmed slightly and covered with a rough coating of insulating "compound," somewhat thicker than the original diameter of the wire. The joint while warm is placed in the lower half of a small wooden block, about 3 inches long and 1 inch wide, fitted internally with a groove for the wire, widening in the middle into a niche about 1½ inches in length for the reception of the compound-covered joint. While the compound is yet warm the upper half of the mould — in shape corresponding exactly with the lower one — is placed on the top, and, by means of a clamp, screwed down until the two wooden surfaces are pressed firmly together. While in this position they are permanently fixed by half-a-dozen ordinary brass screws, and the compound having hardened, the clamp is removed and the joint complete. The cavity in the interior of the block in which the copper ends meet being completely filled with compound, the insulation is all that could be desired, numerous experiments, carried out by the author, having satisfactorily tested the electrical qualities of the arrangement. The cost is thus reduced to a very low figure, and by means of the wooden covering all danger of "leakage" or separation of the wires through bending is obviated. The joint was not, of course, applicable—except in cases of emergency—to submarine cables, but as far as the author could judge, was all that could be desired for the purposes for which it had been designed. The adjourned discussion on Mr. Latimer Clark's paper on "Clamond's Thermo-electric Battery" was then resumed, occupying the remainder of the evening.

CUBA SUBMARINE TELEGRAPH.

The following is from the report of the directors for the half-year ending 30th June, presented at the general meeting on the 17th of August: 7

The accounts show that the gross receipts amount to £14,150, and the expenses to £2,848, leaving a sum of £11,302, out of which the directors have placed £3,155 to the credit of the reserve fund, increasing the fund to £5,000. The balance, after providing for the preference dividend, will admit of a dividend on the ordinary shares at the rate of six per cent. per annum, and leave the sum of £852 to be carried forward to the current half-year's account. They recommend that dividends be declared accordingly, payable 18th instant. In April last the new cable contracted for with Messrs. Hooper's Company was successfully laid from Cienfuegos to Santiago de Cuba, and has continued to work satisfactorily. At the same time, the old cable was cut and the ends landed at Cienfuegos, thereby establishing duplicate means of communication between Havana and Santiago, as contemplated by the directors' special report of 2d June, 1874. In the course of the half-year interruptions have occurred on the lines of contiguous companies, but, being short of duration, have not materially affected the revenue of the company. The last half-yearly meeting having been held so recently, there is little to report on this occasion. The business of the company, as will be seen, has made satisfactory progress during the half-year, and the directors have every reason to believe that such will continue.

SUBMARINE CABLES AND INTERNATIONAL LAW.

Oct 24/76 — Over 233

THE ownership of property on land is often a difficult question even for our elaborate legal machinery, but the question of ownership at the bottom of the sea must some day arise to puzzle our most acute international lawyers. Millions of pounds worth of valuable property now lies at the bottom of the sea in the form of submarine cables, and stands in the names of various joint-stock companies, and of our own and foreign governments. As long as cables live and die a natural death, or are peaceably picked up by the representatives of those who paid for them, no legal questions arise. But cases have occurred where cables have been cut by fishermen to clear their nets, and by ships to clear their anchors, and even in one instance damaged by a ship dredging for one cable and hooking another. The fishermen have generally got off through not being detected, as they have generally operated far from land. Ships that have hooked cables with anchors have been known to hang on to a shore end for six tides, and defy those sent to them to ask them to let go, and if the fishermen could be detected, it is doubtful if they could be made liable. Cables have been damaged by ships breaking through them close to land in broad daylight. On January 5, 1858, the Dover and Calais and Dover and Ostend cables were both broken close to the South Foreland by a sailing ship that drove from the Downs. Since then the North Sea cables have often been broken by anchors, and under certain circumstances a few ships have had actions brought against them—we believe only when they have broken cables within the jurisdiction of the Crown. This it appears extends to three miles from the coast. Thus the secretary of the Commissioners of Woods and Forests, when writing to the Lords of the Treasury in 1855, after stating that the shores of the sea between high and low water belong to the Crown except where by grant or usage they may belong to subjects, goes on to state that "With respect to the bed of the sea from low-water mark, I apprehend the Crown title is indisputable, and that it cannot lawfully be permanently occupied by a subject without license from the Crown. As an illustration of the Crown's right to the bed of the sea, I beg leave to enclose a copy of the Cornwall Submarine Mines Act of last session, which declares that as between the Crown and the Duchy of Cornwall, mines between high and low-water marks belong to the Duchy, but that mines below low-water mark belong to Her Majesty "as part of the soil and territorial possessions of the Crown," and by the 42nd section of the Atlantic Telegraph Act, 1857, it is provided that it shall not be lawful for the company to execute any works whatsoever on the bed or shore of the sea, or of any navigable river so far as the tide flows, without consent in writing of one of the Commissioners of Woods."

So far, then, it seems clear Government claim authority over the ground within the three miles from shore—the old reputed distance of cannon-shot—but what about the sea beyond? Can a man if he negligently or even wilfully destroys a submarine cable be made amenable to law, and if so by what country is he to be prosecuted? Does the flag cover the deed and render the person liable to the Government under whose flag he sails. But without either negligence or malice civil cases may arise. Only last year a piece of cable belonging to the Direct Spanish Company which, although sealed up and ending in the sea, was never intended to be disturbed, was dredged up by accident by a ship at work on other cables, and those in charge supposing it to have been a piece of abandoned cable picked up some portion of it and brought it to England, and the case nearly led to solicitors' letters passing. The trial of such a case would have been very interesting and important. With the numerous cables now down, some lying parallel and not far from one another, it is quite possible that in dredging, a ship may catch a wrong cable, and the legal question that would arise in the case of a long interruption of communication on an important line, would, it appears to us, be very difficult to decide. May not a ship dredge where she likes in the search of a cable?

But another case may be put. Cables now cross one another at right angles. The Marseilles and Algiers cable crosses the Gibraltar and Malta. The Direct Spanish crosses the French Atlantic; and a cable from France to Denmark boldly runs over some half dozen North Sea cables. Now if the lower cable gets out of order near a crossing and has to be picked up, it would be almost impossible to pick it up without cutting it or cutting or breaking the other. The only safe process no doubt would be to pick up to within a short distance of the cross cable, cut and buoy, and then grapple for it again on

UNDERGROUND AND OVERGROUND TELEGRAPHS.

DECIDEDLY the question of underground versus overground wires is growing to a head. The severe test that our overburdened telegraph poles have been put to by the weather resulting in great gaps being made in important lines, the delay to the special train carrying the Empress of Austria on the Great Western, through the fall of telegraph poles across the permanent way, and finally the accidents in the metropolis, through the breaking of overhead wires, have all served to draw public attention to the matter. The press have frequently alluded to it, and even in the House of Commons the subject has cropped up, and Lord John Manners hinted, in answer to a question, that subterranean lines would be more employed in future than they hitherto had been.

We have been so long accustomed to considering overground wires, in the country at least, as the best and only way of constructing telegraphs, that the idea of subterranean wires only comes to the front now and then, when the question is prominently thrust before the public by the interruptions caused by the overground system failing seriously, in spite of the numerous routes which our great network of telegraphs gives between any two important towns. These great interruptions have, however, become more frequent, although they occur, we admit, at considerable intervals. But if we consider that wires have constantly to be added to the poles, which, although scarfed and repaired at times, must on the whole be constantly growing weaker, it is certain that these interruptions must become more and more frequent. On some lines there are 18 or 20 wires on one set of poles, and on the Great Eastern line, near London, the wires nearly touch the railway embankment, from the number that have been placed on the poles. On many lines telegraph poles run on each side of the railway, and soon therefore, a third set of poles would have to be erected.

The telegraph lines on the railways are maintained by the railway companies at so much per mile for the Government. Who these lines belong to it is difficult to say. They were erected by the telegraph companies, and the Government paid the telegraph companies for them; but if the Government wished to remove them, we suppose they could not do so, even if they were worth taking down.

If the Government require more wires, they can obtain them by paying the railway companies, or they can go along the high roads. This they do to a great extent, but principally by overground lines. Now if overground wires are bad along railways, they are ten times more objectionable along high roads, at least in a mechanical and electrical point of view. A railway, with its straight lines and easy curves, is well adapted for overground lines; but our tortuous English lanes and roads, with trees and hedges, are excessively ill adapted for this purpose. Sharp turns at right angles have to be made, which the ordinary insulators that can be used on straight lines or easy curves cannot stand, and therefore shackles, giving less perfect insulation, have to be employed. Again, even the poles are subject to considerable strain, even with only one or two wires, at these sharp angles, and the staying of them is difficult, as the poles have to be kept clear of the road, and are thus thrust close to the hedges, whilst even to get a stay into a ploughed field the permission of some landowner has to be obtained. Trees have naturally to be avoided if possible, and when even to save great strain on the poles it is desirable to cut a corner off, a wire has to hang over private property. In the case of trees, permission has to be obtained to cut them; and even in cutting the corner off the landowner has to be applied to. Thus, what with permission for stays, cutting of trees, and cutting off corners, the number of permissions to be obtained is quite as formidable a work as erecting the telegraph; and, indeed, it was at one time so formidable, that an eminent novelist and popular writer, at that time in the Post Office service, was selected to go through a whole district to coax the country gentlemen into giving the necessary permission for erecting the Post Office telegraphs; so that in fact it may be said that Her Majesty's telegraph lines live out in lodgings on sufferance.

No amount of ingenuity or mechanical feeling can make a telegraph line along a crooked country road look either picturesque or mechanical, but very often there is not much mechanical feeling expended on it, and one pole bending one way and another leaning the other, with insulators starting

Le câble de Rio-Grande do Sul à Montevideo dont nous avons annoncé l'interruption dans notre dernier numéro est rétabli depuis le 10 de ce mois. Quant au câble de Madras à Penang, il est encore interrompu.

Pendant le mois qui vient s'écouler, il s'est produit, en outre, plusieurs interruptions importantes sur les lignes sous-marines. Ainsi, le câble de Banjoowangie, Java, à Port-Darwin, Australie, est interrompu depuis le 27 Avril et, pendant cette interruption, les dépêches ne peuvent parvenir en Australie qu'en empruntant à Pointe de Galles ou à Singapore les paquebots de la poste. Le câble d'Amoy à Shanghaï a subi également une interruption, mais de très-courte durée.

D'un autre côté, le câble de Brest à St-Pierre-Miquelon, dit câble transatlantique de 1869, est interrompu depuis le 26 Avril, et, en outre, tous les câbles de Terre-Neuve au Cap-Breton appartenant à la Compagnie anglo-américaine ont été interrompus du 4 au 9 de ce mois, en sorte que pendant ces cinq jours, toutes les communications directes avec les Etats-Unis et l'Amérique ont été réduites au câble de la Compagnie Direct United States Cable.

1876

* * *

Le câble de Penang à Singapore interrompu dans les derniers jours du mois d'Août a été rétabli au commencement de Septembre; mais celui de Madras à Penang dont l'interruption remonte à la fin du mois de Mars n'a pas encore pu être réparé. Pour remédier aux inconvénients de cette interruption, la Compagnie a organisé à partir du 1er Septembre un service spécial de paquebots entre Rangoon et Penang. Les départs ont lieu tous les 4 ou 5 jours.

La câble des îles Orkney et Shetland a été rétabli le 1er Septembre.

* * *

Les communications sous-marines et autres grandes lignes internationales ont encore subi dans le mois qui vient de s'écouler un assez grand nombre d'interruptions qui, la plupart heureusement, n'ont pas été de longue durée. Pour plus de clarté, nous reproduisons ci-dessous la liste de celles de ces communications qui sont actuellement interrompues ou dont la situation a subi des variations depuis la publication de notre dernier numéro.

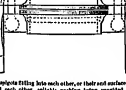
Ironmonger. June 25. 1881.

Pipe-joints.—5102.—December 7, 1880.—Nicolas Talard, of Boulevard Magenta 47, Paris, mechanician.—According to this patent the ends of pipes may be readily secured together, without the use of screw-bolts or screw-couplings, so that the joint may be rapidly and effectually connected and disconnected. For this purpose the ends of the pipes may either have



sockets and spigots fitting into each other, or their end surfaces may merely butt against each other, suitable packing being provided between the meeting surfaces to make a tight joint. The end of the one pipe has lateral lugs, to which are pivoted links, the free ends of which carry eccentrics or cams that can be turned by keys or levers. The end of the other pipe has projecting jaws, between which are introduced the links of the other pipe, whereupon the eccentrics or cams are turned by the keys, so as to press against the jaws with sufficient force to bring the two ends of the pipe tightly together, and thus make a perfectly tight joint. By turning the cams or eccentrics in the contrary direction the joint is readily disconnected again. The levers for actuating the eccentrics may be fixed thereto, in which case they are arranged to lie close against the sides of the pipe, after the joint is tightened up.

Nous reproduisons dans le tableau ci-dessous la liste des grandes communications internationales actuellement interrompues ou dont la situation a subi des modifications depuis notre dernier numéro:

La *deutsche allgemeine polytechnische Zeitung* annonce qu'outre les deux lignes souterraines de Berlin-Halle et de Berlin-Potsdam établies en 1876, l'Administration allemande se propose d'en établir quatre nouvelles et elle ne doute pas que les crédits nécessaires à cet effet ne soient autorisés par le Reichstag [3]). Ces quatre lignes seraient les suivantes, Berlin-Hambourg-Kiel, Berlin-Leipzig, Halle-Saale-Francfort s/M (par Cassel) et Berlin-Magdebourg. Cette dernière ne consisterait que dans la prolongation jusqu'à Magdebourg de la ligne Berlin-Potsdam. La construction de ces lignes souterraines serait confiée à la maison Siemens et Halske, qui ferait fabriquer les câbles nécessaires dans les usines qu'elle possède en Angleterre.

* * *

Les steamers la *Seine*, l'*Hibernia* et la *Kangoroo*, appartenant à la Telegraph Construction and Maintenance Company, sont actuellement occupés, les deux premiers à la pose, sur les deux sections Suez-Aden et Aden-Bombay, d'un second câble destiné à doubler les communications appartenant à la Compagnie Eastern entre l'Egypte et les Indes britanniques et le troisième à la pose d'un câble entre Rangoon et Penang qui a également pour but de doubler la communication Madras-Penang de la Compagnie Eastern Extension.

* * *

[1]) L'interruption totale qui s'était produite le 22 Novembre dernier a cessé le 1er Décembre et le câble a repris sa situation antérieure, c'est-à-dire qu'il ne fonctionne qu'irrégulièrement et par intervalles.

[2]) Les communications par cette voie sont rétablies au moyen d'un nouveau câble (voir la nouvelle précédente).

[3]) Les crédits ont été effectivement demandés au Reichstag, sous forme de l'autorisation d'un emprunt de 8 millions de marks (fr. 10 millions). La question a été renvoyée à l'examen d'une Commission. *(Note du Bur. internat.)*.

Nous trouvons dans «The Telegraphist» du 1er Novembre sur la ligne souterraine qui relie Liverpool à Manchester quelques détails qui offrent d'autant plus d'intérêt que dans les améliorations et les réformes du service télégraphique la question de la substitution des lignes souterraines aux lignes aériennes est une des celles dont on s'est le plus occupé dans ces derniers temps.

La ligne souterraine de Liverpool à Manchester est une ligne de 14 fils; elle a été établie en 1871 et depuis cette époque aucun des fils n'a subi d'interruption. Le câble qui la compose a été fabriqué dans les ateliers de la Gutta-percha Cy, et sa composition diffère complètement de celle des câbles employés auparavant pour les lignes souterraines; elle ressemble beaucoup à l'âme d'un câble sous-marin qui aurait été cousue et tordue. L'âme se compose d'un toron de fils de cuivre recouvert de gutta-percha du No 7 de la jauge de la Compagnie [1]). Après sa fabrication, il a été plongé dans un bain de vieux goudron de Suède mélangé avec de la poussière de liége pour plus de consistance. Ainsi enduit, il a été recouvert de deux couches, enroulées dans des directions opposées d'une étoupe goudronnée fabriquée ad hoc et pourvue d'une double bordure. Le câble ainsi formé a été placé dans des tuyaux en fer ou dans des tuyaux en terre. Sur les $36._{121}$ milles ($58._{180}$ kilom.) qui composent la longueur totale de la ligne, environ 10 milles (16 kil.) sont formés de tuyaux de fer neufs, 4 ($6._{440}$ kil.) de tuyaux de fer vieux et 22 ($35._{420}$ kil.) de tuyaux en terre. Toutefois, là où l'on pouvait craindre l'influence des eaux stagnantes le fer a été remplacé par du plomb. La route sous laquelle le câble a été enfoui traverse dans sa plus grande partie des terrains bas, où les pluies sont très-fréquentes, en sorte que l'eau pénètre dans les tuyaux et y reste d'une manière à peu près continue, même pendant les chaleurs de l'été. C'est là une circonstance particulièrement favorable à la conservation de la gutta-percha et au développement de ses propriétés isolantes. Pendant toute la durée de la pose, le câble a été soumis à des essais fréquents, faits avec le plus grand soins. D'après M. E. Grave, la dépense totale d'une ligne souterraine de ce genre serait le sextuple de celle d'une ligne aérienne.

[1]) D'après les tableaux insérés dans le Handbook of practical telegraphy de M. Culley et qui lui ont été fournis par un agent de la Compagnie Gutta-percha, le fil No 7 a un diamètre en pouces anglais de 0.171 (4mm,32); le poids du cuivre est de 52 et celui de la gutta-percha de 59 livres par mille (respectivement 14kil.,650 et 16kil.,623 par kilomètres). *(Note du Bur. internat.)*.

IMPRIMERIE RIEDER & SIMMEN A BERNE.

lectricité statique des piles au lieu de l'électricité dynamique, amène M. Ehlers à la conclusion que les dernières investigations du ce célèbre électricien dans la matière sont encore un secret.

6. *Méthode de Sir William Thomson pour sonder les grandes profondeurs de la mer avec du fil de cordes de piano.* (Electrical News, vol. I, page 64).

Le fil employé pour les cordes de piano présente quelques avantages sur les cordes dont on se servait autrefois, parce qu'il est très-mince et lisse et n'offre par conséquent qu'une petite résistance à l'eau. La machinerie pour faire descendre le fil est disposée de telle sorte que le tambour sur lequel le fil est enroulé s'arrête automatiquement quand la sonde a atteint le sol. Une aiguille indique alors la longueur du fil déroulé.

7. *Rapport de Sir William Thomson sur les expériences faites sur le câble direct des Etats-Unis.* (Electrical News, vol. I, pages 205 et 213).

Les expériences ont eu lieu les 16 et 17 Septembre dernier. Elles ont été beaucoup contrariées par la présence de courants terrestres.

Après 5 heures d'expériences, Sir William Thomson a obtenu les résultats suivants :

Résistance de la gaîne isolante: 5445 à 8470 millions unités Siemens par nœud.

Résistance du cuivre: pour la longueur totale (2420 nœuds) 7300 unités Siemens ou 3.02 unités Siemens par nœud.

Capacité électrique: du câble entier 991 microfarads ou 0,41 par nœud.

8. *La durée des câbles.* (Telegraphic Journal, vol. III, page 169).

La durée des câbles est très-irrégulière. Tandis que celle des uns ne peut se compter que par mois, par jours ou même par heures, d'autres servent depuis 20 ans. Les causes de la perte des câbles ne doivent pas être cherchées dans la gutta-percha qui, protégée contre l'oxygène et les variations trop vives de température, ne s'altère point avec le temps, mais dans l'armature en fer et la constitution du sol sur lequel le câble repose. A la suite des expériences faites depuis vingt-cinq ans sur les câbles, on peut leur attribuer une durée moyenne de 15 ans. Mais il est permis d'espérer que l'on parviendra à doubler et même tripler cette durée.

(A suivre).

DEEP SEA CABLES.

The question of cheaper and yet more durable cables than our present types must constantly form a subject for discussion and invention. The present type of Atlantic cables has answered undoubtedly the requirements of Atlantic telegraphy: for as long as monopoly existed the price of the cable was not of great importance; and as regards durability, they have also been tolerably successful, in spite of one having been out of order for three years. But other localities show that a cheaper cable is required, for the ordinary shares of our long-line companies remain steadily at a discount.

Light cables—cables without any outer sheathing—are suggested as the remedy, and against the present types, besides their expense, it is argued that the steel or iron, corroding at places where they hang over uneven ground, expose the cable to the chances of gradually dropping to pieces, and undoubtedly some of the old iron-covered cables, which had no protection from rust, and which were laid very tight, suffered greatly from this cause. The cable in places gets heavier, by the coral and marine vegetation that clings to it, whilst getting weaker. The protection afforded by yarn and asphalte has, no doubt, lessened this danger; but the yarn at some places in a few years becomes rotten, and the least disturbance removes it. Suppress the iron wires altogether, say the light cable advocates; but then what are we to place instead of it?

An ordinary guttapercha-covered copper wire will scarcely support two miles of its own length in water. If the ship has to be stopped for a fault of insulation, or even for a false alarm, the line would therefore simply break. Something more is required, therefore, even to lay the wire. Some suggest hemp outside, and others steel between the copper and the insulating material—Allan's patent. There are difficulties with both. The hemp, if laid up loosely, will not support the guttapercha, and, if laid tight, is liable to distort itself into kinks. We do not say the difficulty may not be overcome. With the Allan cable, the electrical conductivity would be greatly reduced with a given diameter of compound conductor, and, consequently, the speed of signalling. The joints are also a difficulty. No doubt the Allan cable would have the advantage when down of having such strength as the steel wires give it well protected from decay. On the other hand, both cables would be quite unprotected from marine insects, and, should a fault occur after they were down, their small absolute tensile strength would render them difficult to feel when dredging. Such cables would also run the chances of marine accumulations on them to weight them, if hanging in festoons over rough ground, just as much as the iron or steel covered cables.

Of the patterns that have been at various times proposed, we have the Allan cable—viz., copper, surrounded by fine steel wires—and this compound conductor insulated with guttapercha. Next, Mr. Siemens' cable of ordinary conductor and insulators, with hemp strands and copper sheathing, and the same with iron or steel wires, hemp and copper sheathing. Mr. Varley proposed a light cable where the insulated wire was laid up with two hemp cords. The cable introduced a few years ago by Mr. Bullevant, of two servings of hemp strands round an insulated wire, with a whipping round the whole, was an improvement on that which Mr. Rowett some years pushed forward, and which consisted of an insulated wire, placed as the heart of an ordinary manilla rope. But Mr. Newall had, previous to this, laid a portion of a line between Candia and Alexandria of almost the same pattern, except that the proportion of hemp to ~~the core~~ was much more scanty than in the samples of Rowett's that were handed about at the time that Mr. Rowett was endeavouring to introduce his cable. The Candia cable was lost. But even this was not the first hemp-covered cable attempted to be laid, for in about the year 1852 or '53, a hemp-covered cable was attempted between Donaghadee and Portpatrick, but it never got further than a few fathoms from the shore, and we once heard one of those engaged on this work describe the attachment of pieces of stone by spun yarn stops to it to moor it.

Another kind of cable of a smaller and lighter pattern than the usual form is described by Mr. Newall in the evidence before the joint committee on telegraph cables in 1861. It consisted of Hooper's core surrounded by very fine steel wires embedded in a single covering of vulcanized Indiarubber. Such a cable would, if it can be manufactured, present many advantages. The steel wires would give it strength and be protected very perfectly from the action of the water quite as well as in the Allan cable, whilst the conductor would remain of copper uncompounded with steel. As regards the cost, we do not suppose that it would, weight for weight of material, be exactly a very cheap cable, but it would certainly be very durable.

The cable lately laid between Australia and New Zealand is the latest attempt to make a cheap cable. It consists of the ordinary core and serving, covered with a sheathing composed alternately of strands of hemp and of steel wires, and the whole served with hemp and asphalte. We can see no particular advantage in this form. The hemp it is very improbable can take its strain with the steel, whilst the principle of the arch as regards the wires touching one another and thus preventing stretch, is even more ignored than in the Atlantic pattern of served wires. In a few years, when the hemp gets soft and rotten, the wires will form a wretched "bird-cage" round the core, and will be easily displaced by any irregular strains that may come on the cable in dredging or hauling in into a hopeless jumble of wire and core.

That improvements will be made in submarine

42

plenty of tanks—she cannot have too many—besides numerous other arrangements for facilitating the work. Yet when a new ship is built or bought she generally is quite devoid of any of these qualities.

The traffic receipts of the Direct Spanish Telegraph Company for the month of February were £679 7s. 9d., against £1,104 1s. 8d. for the corresponding period of last year. The Santander Lizard section was interrupted from the 3rd to 27th of February.

The traffic receipts of the Great Northern Telegraph Company for the month of February were £303,090fr. as against 254,643fr. for the corresponding period of last year.

At an adjourned meeting, on February 23rd, of the Western and Brazilian Telegraph Company, the accounts for the year ending 30th September last were adopted.

At the meeting, on February 29, of the Mediterranean Extension Telegraph Company (Limited), the usual half-yearly dividend on the Eight per Cent. Preference Stock, and a dividend at the rate of 3 per cent. per annum on the ordinary shares were declared, and £500 was carried to the reserve fund, raising that fund to £8,488.

The traffic receipts of the Brazilian Submarine Telegraph Company (Limited), for the month of February, amounted to £12,443, as against £9,857 for the corresponding period of 1875.

The number of messages passing over the lines of the Cuba Submarine Telegraph Company (Limited), during the month of February was 2,642, estimated to produce £2,500, against 2,080 messages, producing £2,195, in the corresponding month of last year.

The Eastern Telegraph Company's traffic receipts for the month of February amounted to £37,044, against £32,765, in the corresponding period of 1875.

The Traffic receipts of the Eastern Extension, Australasia, and China Telegraph Company (Limited) for the month of February amounted to £19,027, and to £16,415 for the corresponding period of 1875.

The directors of the Eastern Telegraph Company (Limited) invite subscriptions for an issue of 6 per cent. first preference share capital in 70,000 shares of £10 each at par. The new capital is required for the duplication of the company's Red Sea and Indian Ocean cables.

The directors of the Brazilian Submarine Telegraph Company (Limited) on March the 3rd, declared an interim dividend of 2s. 6d. per share or 5 per cent. per annum, free of income tax, for the quarter ending 31st December, 1875, and payable on Saturday, the 25th instant.

The report of the Indiarubber, Guttapercha and Telegraph Works Company (Limited) has been issued to the meeting on the 14th inst., and shows that the result of the year's trading is a net profit of £42,617, which the Directors propose to apply to the reduction of the amount of £66,799, standing at the debit of profit and loss account on 31st December, 1874. The sum of £8,724 has been written off from the Company's property for depreciation as usual. The sales for the past year, it is mentioned, not reckoning the Peru and Chili Cables, amounted to £291,001, as against £258,854 for the year 1874, and it is added that the general business of the Company has been fairly remunerative.

The cable from Vigo to Carcavellos broke down on the 5th of February.

The Para Pernambuco cable broke down on the 13th of November, and was repaired on the 18th of February, but on the 24th it broke down again.

The report of the *Great Eastern* Steamship Company (Limited) states as follows:—"The directors, in submitting the accounts for the past year are glad to report that, as explained at the special general meeting, held on 8th December last, all matters connected with the defalcations of the late Secretary have been settled, and, after paying a dividend of 5 per cent., declared 14th August last, there is now a balance to credit of Revenue Account of £7,784, and a cash balance on capital account of £13,284. Until the ship is again employed, the directors think it better not to reduce the balance in hand by paying a dividend. The ship was delivered to this Company at Milford Haven by the Telegraph Construction and Maintenance Company in August last, and she has since been placed upon a gridiron that has been constructed for her within the works of the proposed Milford Docks, which are now in progress, and the directors trust that in a short time a graving dock will be completed sufficient for her accommodation. The hull is now being well cleaned and painted, and such other repairs done to her as will fit her for sea. Several proposals have been made to the directors for the employment of the ship, but as yet no arrangement has been concluded: the matter is having the best consideration of the directors."

The *Oesterreichische Landwirthschaftliche Wochenblätter* states that Dr. Virson, Superintendent of the Italian Experimental Silk Farm at Padua, has

43

Underground Telegraphs.

The two valuable practical papers, "Underground Telegraphs," by Mr. Willoughby Smith, and "Underground Telegraphs in France," by Mr. John Aylmer, C.E., of Paris—which were read before the Society of Telegraph Engineers at their last meeting, on the 28th ult., has served to bring again into prominence the subject of covered telegraph lines.

Taking up a statement of Mr. Prescott's which appeared in the American *Journal of the Telegraph* some six or eight months ago, that the "use of underground telegraph lines had thus far been attended with very unsatisfactory results," Mr. Willoughby Smith sought to establish, and undoubtedly succeeded in establishing, the fact that underground telegraph lines need be attended with no greater risks than open lines—nay that, were the proper material only employed, and due care taken in the execution of the work, there is no reason why covered lines should not be made as safe and durable as need be desired. The most interesting feature, however, of Mr. Willoughby Smith's communication was the argument which he brought forward against the employment of tar on gutta percha covered wire. A covering of tarred tape is, as is well known, all but universally adopted at present as the final protective covering. This, it is alleged, is a grave mistake; for by reason of its use the insulation resistance is materially diminished, and the germs of decay, which in time lead to the complete destruction of the coating, are implanted in the gutta percha. The tar ought to be abandoned, and in its place tannin, whose employment was stated to have been highly satisfactory, ought to be adopted. In the valuable address delivered some time since by Professor Abel, at the Society's opening meeting, this same subject was dealt with, and the state of our knowledge with reference to the causes of decay in gutta percha was shown to be crude in the extreme.

Granting, however, that tar is an objectionable feature in the manufacture of gutta percha covered wire, was there not some point in what was remarked, by one of the speakers in the animated discussion which followed, that surely then Chatterton's compound was not altogether an unmixed advantage? Chatterton's compound consists of one part of Stockholm tar to one of resin and three of gutta percha, and has long been regarded as the panacea for every evil that could befall gutta percha covered wires. No coating can be considered complete, it is said, no wires can be welded homogeneously together, without Chatterton's compound; and if tar is the *bête noir* it is now stated to be, what becomes of the influence of Chatterton's compound? It is all very well to be told, as Mr. Willoughby Smith told us the other evening, that "in the compound the sting of the tar was taken out." It is a pity that the same process of sting-abstraction could not be applied with equal success to the tar in the tape. No, we shall wait for a few further data and a few additional experiments before condemning the tar wholesale and making it accountable for all the mischief; and we will be content to look for the deterioration of the gutta percha, to a very great extent at least, in the cheap and consequently indifferent material which has never been properly tested, and hasty manufacture over which no efficient check has yet been introduced.

No one will now attempt to call in question the possibility of manufacturing really good covered wires: the battle of india rubber and gutta percha need not be fought over again, for the improvements effected in the latter have been so decided of recent years that its position is well-nigh unassailable by its old rival. If danger is to be anticipated from any quarter, paraffin and the products of paraffin will probably show it the most dangerous front. Meanwhile, every one will admit that covered wires as good as need be looked for in the existing state of our knowledge can without difficulty be manufactured, and no one will deny that their laying is a matter which requires nothing more than care to be attended with success. When, therefore, the need for underground telegraphs on a more extended scale than at present does arise, either from the crowded state of the open lines on every

for the testing apparatus occupied the front end of the wagon, opposite the rear entrance. The mirror galvanometer, however, was not placed directly on the table, but upon a small stand just above the latter, and supported by a stout iron tripod and rod passing through a small circular opening in the table. The tripod rested upon the ground beneath the wagon, and quite independent of the latter, so as to give the proper steadiness to the instrument. The graduated scale which receives the reflected spot of light from the mirror occupied a place on the table opposite the galvanometer; while back of the latter, and in front of a small opening in the same, was placed the lamp whose reflected light was thrown upon the scale. Shunts or artificial resistances representing exactly 1-9th, 1-99th, 1-999th of the resistance of the galvanometer were placed in front of the latter and in connection with the same, so that when one or the other was placed in circuit with the galvanometer, the current passing through the latter was reduced to 1-10th, 1-100th or 1-1000th, as the case might be, of what it would be were the galvanometer used alone. The other apparatus was placed on the table between the galvanometer and scale, and the speaking apparatus on the battery chest, whose cover also served as a table.

Testing the resistance of the conductors.—According to the principle of the Wheatstone Bridge (Fig. 1), the relation existing between the resistances in the different arms of the bridge is as follows:

$$r : \rho = R : x$$

r and q representing any constant and convenient resistance; R a variable resistance, and x the unknown resistance whose value is sought. From this we have:

$$x = R\frac{\rho}{r}$$

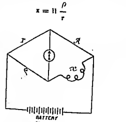

Fig. 1.

In order to obtain the resistance of the conductor alone it is necessary to eliminate any other unknown resistance, such as that of the earth, from the measurements. This may be done by connecting two of the conductors together, when the result obtained will represent the sum of the resistances of both conductors, and the earth is not connected in circuit at all. All of the Halle-Berlin conductors were tested in this manner, and their separate resistances ascertained afterwards by calculation. If we designate the resistances of any three conductors selected at random by I, II, III, the results of the measurements may be written as follows:

(1) $I + II = A$

(2) $I + III = B$

(3) $II + III = C.$

and subtracting (2) from (1), we have:

(4) $II - III = A - B.$

Now adding (3) and (4), we find:

$$II = \frac{A + C - B}{2}$$

And substituting this value in (1), gives:

$$I = \frac{A + B - C}{2}$$

And in (3):

$$III = \frac{B + C - A}{2}$$

To determine the resistances A, B and C, that is, the values of x in the formula above, the apparatus was connected up as shown in fig. 2, with a battery of 10 cells.

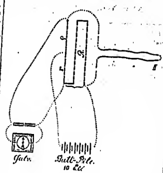

Fig. 2.

If we now take the proportion

$$r : \rho = 1 : 10,$$

then $\frac{\rho}{r} = 10$ and $x = 10\,R$, and if we vary the resistance R in the rheostat until the spot of light is brought to zero, finding when this is the case that $R = 52$ (this figure being taken as an example only), we should then have:

$$x = 10 \times 52 = 520 \text{ Siemens' units.}$$

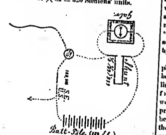

Fig. 3.

In making the insulation tests the connections were arranged as represented in fig. 3, and 100 cells of battery used instead of 10, as in the former test for conductivity. The constant of the instrument was now taken, which consisted in placing the battery in circuit with the galvanometer and a resistance of 100,000 Siemens' units, and noting the deflection. The galvanometer was shunted with the 1-999th shunt, so that the current circulating in its coils was only 1-1000th of that in the rest of the circuit, or in other words, was equal to what would have been obtained if the same battery and instrument without a shunt had been included in a circuit of 1,000 × 100,000 = 100,000,000 Siemens' units.

The cable with the Halle end insulated was now joined in circuit in place of the above mentioned resistance, the galvanometer shunted with the one-ninth shunt and the deflection again observed. It will, of course, be seen that under these conditions the strength of current in the galvanometer coils was the same as would have been obtained had the instrument without any shunt been joined directly in circuit with a resistance ten greater than that of the gutta percha cover.

Representing the deflection first obtained by C, that with the insulated cable in circuit by L, and the resistance of the core itself by W, we have

$$\frac{C}{L} = \frac{10\,W}{100 \text{ millions}} \text{ or } W = \frac{G}{L} \times 10 \text{ millions Siemens' units,}$$

supposing, of course, that the deflections on the scale are proportional to the strength of current circulating in the galvanometer coils. We give here one illustration of the application of this formula. On the 21st of May, 80 miles of cable was laid and tested, the constant of the instrument was 460°, and with the No. 2 core of the cable in circuit the deflection was 200 degrees, or G = 460 and L = 200 when over

$$W = \frac{460}{200} \times 10 \text{ millions} = 23 \text{ millions Siemens' units.}$$

The resistance of the gutta-percha does not remain constant, it diminishes very sensibly with increase of temperature, and increases in the same manner with its fall, so that it is always necessary to take the question of temperature into consideration when measuring gutta-percha if we would avoid serious error.

From the Telegraphic Journal.

Battery Versus Magneto-Electric Current Machines.

The relative values of batteries and magneto-electric current machines for telegraphic and manufacturing purposes is a question which has excited considerable difference of opinion in the electrical world.

The word "battery," although it does not convey a definite idea to the unscientific mind, nevertheless is well understood by electricians and telegraphists to signify an arrangement for generating electricity by means of chemical action, whilst the expression "magneto-electric machine" is understood to represent the idea of an apparatus for generating electricity by mechanical force.

As regards the telegraph system, so long as the employment of the telegraph was limited, and the number of instruments in an office was consequently also limited, the annual cost of maintenance of batteries formed but a comparatively small item in the general working expenses of the establishment; but, at the present time, when the number of instruments at head offices may be numbered almost by hundreds, the substitution of mechanical for chemical power becomes a question which may not be passed over without consideration.

The question when carefully considered, resolves itself into one of £ s d. Can electricity, for working telegraph instruments, be produced the more economically by batteries or by magneto-machines? To answer this query, several points must be considered. Setting aside the employment of magneto-machines at small offices, we will confine our attention to their use at large offices, where some hundreds of battery cells are employed.

To work a number of instruments properly, we must have the means of varying the electric power according to the requirements of each circuit, the shorter circuits requiring obviously less power than the longer ones; climatic consideration may alter conditions, and we may require to add power to the circuits should their insulation fall low.

45

Ocean Telegraph Cables.

As we have received several inquiries in regard to the details of the submarine telegraph cables, we will condense some information on this subject in so far as it has reached us. N.Y.B. June 77

Between the United States and England.—By land lines to Sidney, Cape Breton; thence by cables to Placentia, Newfoundland; thence by three cables to Valentia, Ireland; thence by land lines to Waxford, Ireland; thence by cable to Haverfordwest, England; thence by land lines to London.

Between the United States and France.—By cable from Duxbury, Mass., to St. Pierre, and thence by cable to Brest, France.

Between the United States and the European Continent.—Besides the direct cable to France, communication may be had via England, as this is connected with various continental states by two cables to Denmark, two to Germany, two to Holland, two to Belgium, one to Norway, one to Portugal, two to Spain, and six to France.

Between the United States and the West Indies.—From Punta Rassa, Fla., via Key West to Havana by cables; thence by land lines to Batabano; thence by cable to Santiago de Cuba; thence by cable to Kingston, Jamaica. From Kingston a series of cables extend to Demarara, South America, touching at Porto Rico, St. Thomas, St. Kitt's, Antigua, Guadaloupe, Dominica, Martinique, St. Lucia, St. Vincent, Barbadoes, Granada, and Trinidad. A cable also extends from Jamaica to Aspinwall on the Isthmus of Panama. When the cable is completed and in working order from Port of Spain, Trinidad, to Ponce, Porto Rico, touching at St. Croix, Cienfuegos, Cuba, and Jamaica, the United States and the West Indies will be substantially united by a double series of cables, so that in case of failure of any one of them, communication will not be interrupted.

Between the United States and South America.—It is expected that soon there will be a complete line of telegraphic communication between the United States and Rio Janeiro, South America; and when another link is laid between Rio Grande do Sol and Maldoondo, Uruguay, the United States will be in telegraphic communication with all of South America, bordering on the Atlantic ocean, north of Buenos Ayres, and with Chili on the Pacific. A singular fatality has thus far attended the laying of the cable between Rio Grande do Sol and Maldonado. The telegraph steamer *Gomas* was first wrecked in laying it, and the *La Plata*, chartered to pursue the work, was wrecked in the Bay of Biscay, the cable and all persons on board being lost.

Until the cable is laid down between Cayenne and Demerara, communication between the United States and other parts of South America must be forwarded via Europe, the cable between Lisbon, Portugal, and Pernambuco, Brazil, furnishing the only means of telegraphic intercourse.

Connection of other Countries.—One cable between France and Denmark; one between France and Spain; two between France and Algeria; two between Portugal and Gibraltar; one between Gibraltar and Malta; one between Algeria and Gibraltar; two between Sicily and Gibraltar; one between Malta and Alexandria; one between Italy and Alexandria, touching at Corfu, Zante, and Candia; one cable between Russia and Turkey, through the Black Sea; one between Norway and Denmark; one between Denmark and Sweden; one between Sweden and Russia; one between Denmark and Russia; one between Sweden and Germany; one between Egypt and India, through the Red Sea and Indian Ocean, touching at Aden; one between Persia and India, through the Persian Gulf, touching at Gwadar in Beloochistan; one from Madras, India, to Penang in the Strait of Malacca; one from Penang to Singapore; one from Singapore to Saigon, Cochin China; one from Saigon to Hong Kong and Shanghai, China; one from Shanghai to Nagasaki, Japan; one from Nagasaki to Hiogo and Yokohama, Japan; one from Nagasaki to Wladivastok, Asiatic Russia; one from Singapore to Batavia, Java; one from Java to Australia; one from Australia to Tasmania or Van Diemen's Land.

The following cables are projected: from Australia to New Zealand; from Ceylon to Australia; from Singapore to Borneo; from Borneo to Luzon; from Luzon to Hong Kong; from Yokohama to Hokodadi; from Siberia, mouth of the Amoor, to Kamtchatka; from Calcutta to Penang; from Hong Kong, China, to San Francisco, Cal., touching at the Sandwich Islands; from Havana to Vera Cruz; from Aspinwall, Isthmus of Panama, to Carthagena, South America; from Panama to Buenaventura, New Granada; from Buenaventura to Callao, Lima; from Callao to Valparaiso, Chili; from England to Virginia, touching at the Azores and the Bermudas; from Portugal to New York, touching at the Azores; from Scotland to Labrador, touching at the Faroe Islands, Iceland, and Greenland.

Communication between England and India is mainly confined to the following routes: First, from Penzance on the southeastern coast of England to Lisbon, Portugal; thence to Gibraltar; thence to Malta; thence to Alexandria, Egypt; thence by land line to Suez, and thence by cable to Aden and Bombay. Second, by cable from Lowestoft, England, to Emden, Germany; thence by land line via Berlin, Germany, Warsaw, Jitomer, Odessa, Kertsch, and Tiflis, Russia; thence to Teheran, Bushire, Henjaum, and Jask, Persia; thence to Gwader, Beloochistan, and Kurrachee, India. This is known as the special Indo-European line, and is worked in one circuit from London to Teheran, a distance of 6,000 miles. From Kurrachee and Bombay land lines extend to Calcutta, Madras, and Paumben; from Paumben a cable extends to the Island of Ceylon; one from Madras to Penang and Singapore; from Singapore cables extend to Saigon, Cochin China, and thence to Hong Kong and Shanghai in China and Nagasaki, Hiogo, and Yokohama, in Japan; one from Nagasaki to Wladivostok, the terminus of the Russian land lines in Siberia; from Singapore a cable extends to Batavia in the Dutch island of Java; from Java one extends to Port Darwin, Australia, and there connects with a land line extending to Victoria, Australia; from Australia a cable connects with Tasmania or Van Diemen's Land. Telegraphic communication exists between Victoria, British Columbia, and Hobart Town, Tasmania, embracing 273 degrees of longitude, thus lacking but 78 degrees of encircling the globe; and when the projected cable from San Francisco to China is laid, the circle will be completed. When this latter enterprise is carried out, the telegraphic correspondence between North and South America and the West of Europe, with China, Japan, and Australia will take this route, as it will be the shortest, cheapest, and most expeditious.

246

Subterranean Telegraphy.—The last portion of the great underground cable from Berlin to Mayence was laid at the latter place on Monday week in the presence of the Postmaster-General of Germany, a numerous staff, and a large number of gentlemen. The Emperor William sent a telegram from Gastein, congratulating the Postmaster-General and those assembled on the completion of the work. This event deserves notice, for the Berlin and Mayence cable is the first long subterranean cable that has been laid down. In 1848 Germany laid down a wire between Berlin and Cologne, but this proved a total failure. The process of manufacturing guttapercha and making cables was then imperfect. For instance, sulphur, the greatest enemy to guttapercha, was mixed with it. The result was that after a few weeks the faults multiplied to such an extent that correspondence became impossible. This created a prejudice against subterranean telegraphy, and more than 25 years elapsed before an underground cable on a large scale could be projected. The cable is about 600 kilometres in length, and passes from Berlin through Halle, Leipsic, and Frankfort to Mayence, the wires twisted together, and covered with hemp and iron. The cost is about six times more than the same number of overground wires would cost. Germany now possesses seven underground lines between its capital and its western frontier.

Aug 77

A New System of Electric Telegraphy.

M. Tomassi has described to the Physical Society of Paris a new system of electric telegraphy applicable to submarine cables of great length. He employs a new relay, the sensitiveness of which is such that 5 per cent. only of the current of a single Minotto element, after having traversed a resistance equal to that of 2,520 miles of Transatlantic cable, and a plate of wood lightly moistened (which represents a much greater resistance), suffices to cause it to act on the printing instruments with the greatest rapidity. A second relay automatically interrupts the current of the local battery after each emission, hindering a spark from being produced in the first relay. This spark, which may occasion inconvenience in a very delicate apparatus, such as the first relay, produces none in the second, because of the energy of the contact, which renders the consequences of the spark absolutely inoffensive. This relay acts in turn on the printing apparatus and on another local battery. The receiving instrument is composed of two electro-magnets, which operate converging metallic points. One point impresses a red and the other a blue trace on the same band of paper, according as the operator transmits the Minotto current in positive or negative direction. Different combinations of these red and blue marks indicate numbers, letters, words, and even entire phrases. The transmitting apparatus automatically reverses the current after each emission, and the emissions are exactly of the same duration.

Submarine Cable Statistics.

Of submarine cables, private parties own 119; miles of cable 59,547; miles of wire 65,535. Governments own 420 cables; 4,442 miles of cable and 5,725 miles of wire. Norway has 103 cables, Sweden 4, Denmark 29, Holland 18, Russia 3, Germany 46, Turkey and Greece 13, Italy 12, Spain 6, France 26, and Great Britain 52. The Anglo-American company has the longest submarine cable in the world, 2,585¼ nautical miles, and has five Atlantic cables in all, besides twelve other cables, a total length of 12,815 miles. The Eastern Telegraph Company has 48 cables, with 21,883 nautical miles.

Nov 77

Underground Telegraphs.

Between Berlin and Halle an underground telegraph wire has been in use for one year, and underground wires are about to be laid between Berlin and the cities of Cologne, Frankfort, Strasbourg, Breslau, Hamburg, Kiel, and Königsberg, thereby dispensing with posts and insulators, and avoiding the cost of their maintenance. The copper wires which convey the electric current are enclosed in wrought iron pipes, and are hermetically enclosed by insulating material, which protects them from the action of air and water, and prevents oxidation.

77 **Underground Telegraph Wires.**—Mr. Stephan, Postmaster-General of the German Empire, is replacing open-air telegraphs by underground wires. Already Berlin is thus connected with Kiel and Hamburg in the north and Mayence in the south. These subterranean telegraphs being comparatively safe from injury, their importance, especially in time of war, is obvious.

The Cable Steamer Hibernia Wrecked.

Dec 77

The Telegraph Construction and Maintenance Company, despatched their cable steamer *Hibernia* October 29th last, from the Thames, having on board the new cable designed to restore communication between the Para and Penambuco Stations of the Western and Brazilian Telegraph Company. The *Hibernia* was wrecked November 22d, in Maranham Bay. No lives were lost.

Réseau télégraphique souterrain de l'Allemagne. — L'Allemagne poursuit activement l'achèvement de son réseau de lignes télégraphiques souterraines. Ces lignes, plus spécialement tracées en vue des nécessités politiques et militaires, rayonnent dans toutes les directions en partant de Berlin. Les câbles sont placés dans le sol à une profondeur de un mètre environ. La pose se fait, lorsque la nature du sol le permet, au moyen d'une machine spéciale qui creuse la tranchée, y dépose le câble et le recouvre d'une manière continue, de telle sorte que la main de l'homme n'ait à intervenir que pour régulariser la surface du sol après le passage de la machine. Sur la plupart des routes, cette machine fonctionne d'une manière très-satisfaisante.

Jan 78

Elle se compose essentiellement d'une locomobile donnant le mouvement à une roue de grand diamètre placée sur un essieu mobile. Cette roue, armée de dents et de palettes, creuse le sol à la profondeur voulue et enlève la terre pour la déverser en arrière sur le câble, qu'un mécanisme spécial dépose au fond de la tranchée au fur et à mesure de l'avancement de la machine. On peut ainsi placer très-rapidement et très-économiquement une grande longueur de câble; les difficultés ne commencent que lorsqu'on rencontre un terrain très-dur et rocailleux, alors il faut renoncer à l'emploi de la machine et creuser la tranchée par les moyens ordinaires, beaucoup plus lents et plus coûteux.

THE DESTRUCTION OF SUBMARINE CABLES.

Feb March 78

Submarine Cables are subject to numerous causes of deterioration. In the first place, on northern shores, there are the banks of floating icebergs, which sometimes extend to a depth of 500 or 600 meters. In their journey southward, these ground and break under water; the broken masses dislodge the cable which crosses their path. This kind of accident often occurs to the Atlantic cables on the coasts of Newfoundland.

Next to ice-banks must be mentioned wear and tear on rocky bottoms. Near the coast-line, says M. Ternant, in a treatise on the repairing of submarine cables, the depth may vary rapidly, so that the cable does not lie evenly on its bed; one end lying on a rock may have to bear the entire weight of the portion of the cable which is unsupported. A continuous to-and-fro movement, arising from the agitation of the sea or from ordinary tides or currents, determines the gradual wearing away, albeit slow, of the external wires. The sheathing once destroyed, the conducting wires yield and break, or the continued attrition of the core lays bare the conductor, making earth and stopping communication. The cable between Bonifacio and Sardinia was interrupted in 1861 from this cause; and the six conductors it contained were broken by the stretching inside the gutta-percha, which only yielded to the strain in picking up. We may further mention as causes of destruction, coral beds, earthquakes, submarine eruptions, and high temperature on tropical coasts.

The enemies in the animal kingdom are not less numerous. A curious observation was made after the laying of the cables on the Brazilian coast. As is known, Brazil was connected with Portugal in 1875. At the same time a series of cables round the coast completed the system from Pernambuco to Para, Cayenne, Demerara, and the Antilles. The observation referred to was made in the Para Cayenne section. It consisted of singular bites due to attacks made by the saw-fish, which abounds in those parts. A similar occurrence to the Singapore Cable in 1871 was described in *Nature* in 1873 (Vol. I., p. 160). Mr. Buckland found among his collection a fish-jaw, from which he detached the saw; and with this he reproduced upon a piece of cable a fault similar to that which had caused the interruption.

In Brazil this kind of fault has become chronic; we gather our information from the engineers in charge of the Sylog. In the first piece which failed, one of the protecting iron wires was wrenched so as to expose the hemp with which the core was served. In the center of this part a piece of bone, apparently the scale of a fish-tooth, was found thrust through the hemp into the gutta-percha. On the same side of the cable, about two inches distant, another piece of bone was found in a similar position. Each of these scales was about one inch in length, and about one-eighth of an inch in diameter.

In another fault, one of the wires was bent inward, the remainder of the strand being slightly deformed and the "lay" taken out. One of the crew, during the heaving in, drew out from the cable a triangular splinter of enameled tooth, about a quarter of an inch thick; this piece was fixed between the wires. On stripping the core, a small puncture was discovered, as if made with a broach.

A third fault was of a more mysterious nature. The cable showed no appearance of being defective. When the external coverings were stripped off, and the core bared, a hole about the size of a pin's head was seen, filled with a whitish substance resembling glazier's putty. One wire of the internal sheathing was found severed exactly over this hole; the external iron wire which lay immediately over was bent into a crook about two inches off. A small portion of the exterior serving was displaced in the region of the fault. On cutting through the core close to the fault, so as to expose the conductor, more of this soft, crushed, pasty matter was found. Two small fragments of hard bony substance were found in the interior serving. These bites showed traces of decomposition; but they were so small that it was difficult to say if the foreign matter was bone or scale. The fragments were somewhat fibrous and semi-transparent: there is little doubt, having regard to other signs, that they came from a fish. The white substance was certainly decomposed dental matter.

These three faults were all found within 15 miles of each other, about 130 miles from Para. A fourth one was found in the deep-sea type; and although no fragments of teeth were discovered in it, the distortion of the sheathing wires showed that it was due to the same causes as the preceding. A fifth fault, picked up 270 miles from Para, half way to Cayenne, was not so evidently caused by fish, although such is just possible. The core in this case was pierced as before, but this time the hole was filled with a black substance; the copper gave signs of indentations like teeth marks. The teeth must have been very strong to have freed themselves. Mr. Warren has told how, after these faults had been taken out, the cable was again interrupted in the following year with five more fish bites at about the same place. From one of these a piece of hard bony substance, an inch and a half long, was taken, while the piece still fixed in the cable was an inch in circumference. Mr. Warren was much puzzled to know by what fish these attacks were made, until arriving at Demerara, where he identified the teeth of the saw-fish, which abounds in these waters and on all the northern coast of Brazil.

47

After the saw-fish, three insects may be mentioned whose misdeeds have been known some years, which were described by Mr. Preece before the Society of Telegraph Engineers.

The *Teredo* is a worm which constructs a shelter in the form of a tube by secreting calcareous matter. The *Xylophaga* is a bivalve. The latter does not penetrate far into the gutta-percha; it only fixes one valve into it. In small cores this is sufficient to produce a considerable loss of current.

The *Teredo* and the *Xylophaga* are found in the Mediterranean, in the Atlantic, and even in the northern seas.

The *Teredo norvegica* is a worm of considerable dimensions, and is armed with bivalves in the form of shells, which enable it to gnaw the hardest wood. It belongs to the class of acephalous mollusks; naturalists count at least twenty-four different species.

The *Limnoria lignorum*, called also *L. terebrans* by Dr. Carpenter, is a little crustacean of the size of an ant, so that it can get through the interstices of the sheathing wires even of the best made cable, and penetrate to the core, through which it burrows. In the Indian Ocean and the Persian Gulf, the *Limnoria* attains larger proportions, and effects excavations of considerable size. It is frequently met with on the shores of Ireland, where several cables have been seriously damaged by it.

CABLE STATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I am not altogether eager to take up the cudgels on behalf of the companies. No doubt, abler men will do that; but I must at once raise the question as to the accuracy of "E. A.'s" strictures as stated in your issue of last week. So far as I know, the managers of the companies do everything your correspondent intimates they fail to do. At all the cable stations with which I am acquainted there are good libraries; whilst, for those who do not care so much for sedentary occupation, we have billiards, besides our boating and athletic clubs. In the evening our piano gives forth no uncertain sound, and, in fact, everything is done to make the monotony of our existence less monotonous. As for selection, what would you have in these days of competition? I know I had to study previous to obtaining my post. "E. A." should know that, even were his statements true in any one case, the majority of managers do take all possible care and interest in the welfare of those in their employ.

TELE.

June 78

Les lignes télégraphiques souterraines en Allemagne.— Les travaux pour la pose du câble télégraphique souterrain de Francfort à Strasbourg progressent activement. A la fin de mai, le creusement de la voie souterraine était terminé à Mannheim, et la pose des fils a été aussitôt commencée.

Le câble est formé de sept fils isolés entre eux, le tout recouvert d'une couche de briques et d'une armure en fer. Il sort des ateliers de l'usine Siemens et Halske, de Berlin, et son transport s'opère à l'aide de grands rouleaux spécialement construits dans ce but.

Les fils, au fur et à mesure que les rouleaux s'avancent, se déroulent d'eux-mêmes, et sont aussitôt répartis dans les canaux souterrains par des ouvriers exercés à ce genre de travail.

Les canaux une fois recouverts, on disposera à l'extérieur, et à intervalles égaux, des marques particulières correspondant à des divisions déterminées du câble, pour faciliter, en cas de dérangement des communications, la recherche du point à réparer.

48

Foreign Telegraphic Notes.

[A]t a meeting of the board of directors of the Anglo-American Telegraph Company (Limited), held March 20th, it was resolved, after placing £37,500 to the renewal fund, to declare an interim dividend for the quarter ending the 31st inst., of 1 per cent. on the Ordinary Stock, and of 2 per cent. on the Preferred Stock, both free of income tax, payable on May 1 to the shareholders, registered on the books of the company on April 1, leaving a balance of about £7,500 to be carried forward to the next account.

The Eastern Extension Telegraph Company will pay for three months ended 31st December a dividend of 2s. 6d. per share, making, with previous payments, a distribution of 5 per cent. for the year 1877, and £30,905 is carried to reserve. The dividend is the same as for the year 1876, when £6,011 was carried to reserve.

The balance sheet of the Great Northern Telegraph Company for the year 1877 shows that the total receipts were, inclusive of £10,409 brought forward, £223,867, while the expenditure was £62,280. The interim dividends, at the rate of 5 per cent. absorbed £75,000, and an extra dividend of 2s. 6d. per share required £20,833; to the reserve fund £14,444 was added; and, after paying directors' remuneration and pension-fund allowance, the sum of £19,277 is carried over.

The severe snow storms and gales in England in the latter part of March caused serious interruptions to the telegraphic communication in various parts of the country, and especially in the West of England and South Wales.

It is said that the Chinese are particularly well pleased with the telephone, and that messages have been sent in China over 500 miles of wire.

The steamers John Pender and Chiltern left Malta, March 13, with submarine cables on board, having been chartered by the Government to lay them at various points in the Levant.

A meeting of South African merchants was held recently in London, and resolutions were passed in favor of the establishment of a telegraph line to Cape Colony. A committee was appointed to represent the views of the colonists to Sir Michael Hicks-Beach, and to press upon the Government the urgent necessity for the early laying of a line of cable to connect England and South Africa, leaving it to the Government to judge whether the cable should be laid on the east or west side of Africa.

The Post Office authorities notify that the cable between England and France and the Channel Islands is interrupted. The English cable also being interrupted, messages can now only be dispatched by steamer.

A message from Berne, Switzerland, dated March 21, states definitely that the Argentine Confederation would be admitted into the International Telegraph Union April 1.

A Grave Mistake.

The Chairman of the Direct Cable, in his remarks at the meeting of that company, held on the 22d of March, said:—Were a cable worked to its very utmost extent and fullest carrying capacity and only a moderate expense of working allowed for, at a one shilling tariff, it would only give a return of about two per cent. per annum, not "twenty per cent," as erroneously stated in the report, published in United States.

Cuba Submarine Telegraph Company.—The number of messages sent during October by this Company was 2,679 as against 2,609 during the corresponding month in 1877.

49

S.S. SHERARD-OSBORN AND CABLE LAYING.

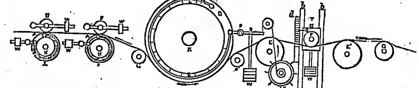
In our first number we stated that the Eastern Extension Company had just added the above-named vessel to the fleet of cable ships.

On Monday, 3rd inst., in response to the invitation of Mr. John Pender, as chairman of the company, a large number of scientific gentlemen and others interested in the cause of electrical progress proceeded by special steamer to Greenwich to inspect the *Sherard-Osborn* and the works of the company. The ship, fresh from the builders' hands, and gaily decorated with bunting in honour of the occasion, excited the unqualified admiration of her visitors, who were none the less pleased that her fittings throughout betokened that strength and utility had not been sacrificed for the sake of mere outward effect. Admirably adapted for the performance of her special duties as a cable ship, the *Sherard-Osborn* is, however, not lacking in the elements of comfort so necessary to those engaged in the arduous work of cable-laying in the burning climes for which she is destined. The four large tanks were as yet empty. At the works, however, to which the visitors next proceeded, the cable which is about to be embarked was rapidly approaching completion, so that the elaborate process could be examined in all its stages. The experience gained during the past few years has shown that the deep sea cable has many foes, and a new feature in the construction of the one destined to form the first cargo of the *Sherard-Osborn* had for its object the defeat of that most pertinacious enemy, the *teredo navalis*. For this purpose, amongst the eight coverings with which the precious copper is protected there has been introduced a wrapper of brass tape, and it is confidently anticipated that this final precaution will baffle even the *teredo navalis*.

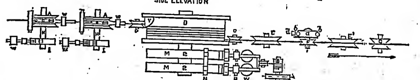
When everything of interest had been thoroughly inspected, the company adjourned to the Ship tavern, where covers were laid for 150 guests. Mr. Pender, as president, was supported by Sir James Anderson, Sir Garnet Wolseley, Sir Spencer Robinson, Mr. Hussey Vivian, M.P., Mr. Donald Currie, M.P., Sir Archibald Michie, Mr. E. J. Reed, M.P., Sir William Thomson, Mr. Julius Beer, &c., &c.

In returning thanks for the Army and Navy respectively Sir G. Wolseley and Sir S. Robinson enlarged upon the debt which either branch of the service owed to men of science, and especially to those who had devoted themselves to the development of the marvellous powers of electricity. Sir A. Michie expressed the obligations felt by the colonists of Australia and New Zealand to the telegraph engineers, without whose labours they could never have attained their present prosperity; and Mr. Donald Currie forcibly urged the necessity of completing our communications by telegraph with the Cape of Good Hope—a necessity brought home just now to the breasts of all Englishmen by the thought of the struggle now going on between our countrymen and their native foes, the vicissitudes of which only came to our knowledge after a lapse of three long weeks.

Mr. Saunders, the electrician of the company, has kindly supplied further information relating to the ship, together with such diagrams and explanations as, we think, will render clear to all our readers the machinery employed to perform the work of laying down and picking up cables.



SIDE ELEVATION



PLAN

The Ship.

The *Sherard-Osborn* is 270 feet long, 32 broad, and 23 deep. The twin screws are driven by engines of 900 horse power nominal. The registered tonnage of the vessel is 875 tons, the gross tonnage, however, is 1,429 tons. There are four cable tanks, and water-tight bulkheads allow water ballast to be used to counteract the loss of weight when paying-out cable.

The Paying-out Gear.

In putting the cable on board for laying, sufficient end having been left out for testing, the coiling is begun from the large diameter of the tank in the direction of the lay of the cable, the turns being placed close to each other until the eye is reached, the latter being generally about one-third of the diameter of the tank and made telescopic, so that it can be gradually lowered as the coil decreases during the progress of paying-out. Each layer is called a flake. The cable is not coiled back upon the eye, but is laid out diagonally on the top of the flake to the side of the tank, and then coiled back to the eye, and so on until the tank is filled.

In laying the cable, the end is brought over a wheel placed over the centre of the tank, and thence along troughs until it enters the paying-out machinery, then passing over the V wheels A A, under the jockey wheels B B, which run on the top of the cable, and by their weight press it into the grooves of the V wheels already mentioned, thus keeping up a slight strain on the cable before it passes on to the paying-out drum D, around which it takes four or five turns, over the wheel E, under the wheel F of the Dynamometer, over the wheel E', and finally over the stern wheel G into the sea.

On the shafts H H of the V wheels A A are fitted friction brakes I I. The paying-out drum has also a double break 2 2. The breaks consist of iron wheels or drums K K K, the peripheries of which are broad and flat. Around these press segments of wood L L L affixed to the steel band M. One end of this band is fixed to the frame-work of the machine at N, and after passing nearly around the drum K is hinged to the lever O, the fulcrum of which is at P, and on the other end of the lever weights W are placed according to the amount of friction required.

Attached to the frame of the machine is a wedge-shaped piece of iron, fitting close to the circumference of the paying-out drum, and called the fleeting knife, its use being to fleet the turns of the cable, so that there shall be a clear space for the cable coming on the drum, and thus prevent the turns overriding each other.

The description of the brake to the paying-out drum D will apply to those for the smaller brakes to the V wheels A A. The amount of friction can be very nicely regulated by means of the wheel R, which has spokes similar to those of a ship's steering wheel, and to prevent heating by friction the brakes run in tanks filled with cold water. On the shaft is a drum S, around which the chain fastened to the end of the lever can be wound, thus lifting the weights and regulating the amount of friction. The man stationed at this wheel watches the indicator of dynamometer T, and lessens or increases the friction according to the amount of strain indicated. A similar arrangement is attached to the small brakes and jockey wheels, by which the jockeys can be lifted and the amount of the friction on the breaks regulated.

The dynamometer consists of the slide *a* carrying the wheel F and weights W working between the two uprights *b b* according to the amount of strain in cwts. on the cable as shown by the pointer *c* on the scale *d*.

The different parts of the paying-out gear are placed relatively nearer each other in the drawing than they are on board ship,

this requiring to be noted more particularly in regard to the wheels E.E′ and C T. It is of the greatest importance that a sufficient amount of slack be paid out to compensate for the inequalities of the bottom. Great attention must therefore be paid to the relative speed of the ship and that at which the cable passes overboard.

To enable the engineers to judge on this point a rotameter is attached to the main shaft of the paying-out drum, which indicates every revolution by striking a bell. Further, pointers on a dial show the total number of revolutions. The engineer, knowing what speed will be given to the ship by a certain number of revolutions per minute of her engines, and counting the number of revolutions per minute of the paying-out drum, the circumference of which he has accurately measured, is able to tell at once whether the relative speeds of ship and cable will give the proper amount of slack; if not, he either increases or diminishes the speed of the ship or the weights on the brakes of the paying-out drum. Sir William Thomson's wire-sounding apparatus enables soundings to be taken so quickly that it is of great service in laying cables; and lately during such operations one ship has proceeded in advance of the other for the purpose of taking soundings, which were at once telegraphed to the rear or paying-out vessel, so that the engineers on board the latter could regulate the amount of brake power necessary to ensure the proper amount of slack being allowed.

Diagrams of the picking-up gear, with the necessary amount of explanation, will be given in another paper.

Laying and Repairing Telegraph Cables. By V. Hoskiær. London: Spons, 1878. The author, who is an officer in the Royal Danish Engineers, has been engaged in laying telegraph wires in the Baltic, the North Sea and off Japan; and he has been well advised to publish, for the benefit of young engineers, the result of his ample experience. As the author's MS. has been revised by Mr. France, manager of the Brazilian telegraphs, there is not the faintest chance of discovering an error either in his statements or formulæ. The appendices, which constitute half the little volume, contain specimens of "records" and journals such as have to be carefully kept on board every ship engaged in laying cables. We by no means begrudge the gallant Dane the honour of doing a thing that should have been done long ago by an Englishman. He has acquitted himself of his work well, and—written in the tongue of the mother of a dozen nations—his book will unquestionably have a success which its well-balanced structure deserves. July

The Brazilian Submarine Telegraph Company's receipts for July were 11,759l., against 9,329l., showing an increase of 2,430l.

The receipts of the Eastern Extension, Australasia, and China Telegraph Company for July amounted to 24,927l., against 22,224l. in the corresponding month of last year, showing an increase of 2,703l.

The traffic receipts of the Great Northern Telegraph Company for July were 18,811l. For the seven months ended with July 31 the aggregate receipts were 118,163l., against 115,335l. and 115,876l. in the corresponding periods of 1877 and 1876.

The receipts of the Direct Spanish Telegraph Company for July were 812l., while the corrected receipts for the corresponding period of last year were 824l.

The estimated receipts of the West India and Panama Telegraph Company for the half-month ended with the 31st ult. were 2,175l., against 2,433l. in the corresponding period of 1877.

78

ELECTRICITY.

The Electrician says that the life of a submarine telegraph cable is from ten to twelve years. If a cable breaks in deep water after it is ten years old, it cannot be lifted for repairs, as it will break of its own weight, and cable companies are compelled to put aside a large reserve fund in order that they may be prepared to replace their cables every ten years. The action of the sea eats the iron wire completely, and it crumbles to dust, while the core of the cable may be perfect. The breakages of cables are very costly, and it is a very difficult matter to repair them in comparison with a land line. A ship has to be chartered at $500 a day for two or three weeks in fixing the locality and in avoiding rough weather, as cables can only be repaired in calm weather. One break in the direct cable cost $100,000.

Subterranean Telegraph Wires in Germany.

In 1876 the first subterranean telegraph wire was laid down in Germany. Recently, subterranean lines have been completed from Berlin to Cologne, from Cologne to Elberfeld and Barmen, from Frankfort to Strasbourg, and from Hamburg to Cuxhaven. Altogether the length of these lines now amounts to 1,551 English miles. Most of the cables consist of seven wires, very few of four only. The difficulties encountered in laying down the cables in marshy or rocky ground, along the streets of large towns, across, or rather under, rivers, and through fortifications, have all been successfully overcome. Next year six other lines are to be laid down, and then the projected system of subterranean telegraphic communication throughout the German empire will be almost complete. The cost of the lines already laid down amounts to about $3,030,000.

politan Gas Companies for the year 1876, and presented to Parliament, the following was the position of each of them ending December 31st.

The Gas Light and Coke Company had of stock and share capital a total of 8,205,000l. authorised, and 6,004,080l. paid up, with 1,436,500l. loan capital borrowed, and 1,125,000l. remaining to be borrowed; the total receipts on capital account amounted to 8,101,480l. The South Metropolitan Company, at the same date, had a total share capital of 460,000l., paid up, with no loans, leaving 40,000l. for issue. The Commercial had a total authorised capital of 530,000l., and of loan 300,000l., of which 611,638l. share and 15,670l. loan had been paid up, making a total of 627,308l. actually paid up. The London had 758,927l. paid up, against 873,342l. authorised, with loans of 78,402l., and 101,122l. remaining to be borrowed. The Phœnix had a capital of 900,000l., out of 1,044,000l. authorised, and 155,000l. loans, and 45,000l. to be borrowed. The Surrey Consumers showed a total of capital of 290,000l., of which 230,000l. were share, and 60,000l. loan, leaving a net of share and loan together to be called up of 20,000l. Taking these figures in a gross total, it would appear that, at the end of 1876, the whole paid up share and loan capital of the Metropolitan Gas Companies was about 11½ millions, and of unissued shares or unissued loans about 3½ millions, ~~thus making the total capital in~~ connexion with London gas supply to amount to, say, 15,000,000l., within but, comparatively speaking, a small fraction.

We next refer to the accounts of the London Gas Companies, just issued for the year 1877. In regard to the Gas Light and Coke Company, while the total authorised share and loan capital remains the same as in 1876, there has been about 300,000l. additional share capital issued, this so far reducing the share and loan capital authorised. The share capital of the South Metropolitan was increased in the year to 750,000l., being 250,000l. more than authorised in 1876. Of this the total paid up is 480,000l., leaving 270,000l. capital unissued. In regard to loan capital this company has borrowing powers to the extent of 250,000l., none of which have yet been exercised. Practically it would appear, therefore, that taking ordinary share and loan capital the financial powers of this company show an increase of half a million, of which but 20,000l. was called up as share capital in 1877, that is, 460,000l. share capital paid up in 1876, as 480,000l. paid in 1877. In respect to the Commercial the authorised share and loan capital (830,000l. and 300,000l.) remains the same as in 1876. But there has been an extra issue of share and loan, making the totals 690,317l. in 1877, against 627,308l. in 1876 paid up and borrowed. The variation in the finances of the London Gas Light Company show little difference in the authorised share and loan capital, but there was an issue of 30,562l. of 4½ per cent. debenture stock in 1877, which with other items of increase and decrease, by conversion, paying off, &c., gives 801,170l. as total receipts in 1877, against 842,178l. in 1876. The Phœnix accounts for 1877 show an increase of 200,000l. share capital, or 1,244,000l., against 1,044,000l. in 1876. But the total receipts on account capital were in 1877 to the extent of 1,121,000l., against 1,055,000l. in 1876. In regard to the Surrey Consumers' the capital and loan accounts present no difference between the two years.

From the preceding figures it appears that, taking the total increase of expenditure, both as regards share and loan capital, of the six London gas companies in 1877, as compared with 1876, the difference is, comparatively speaking, of little account. This is certainly an element of strength, and compares favourably with the statistics of railway capital, which we gave on page 135 *ante*. In the case of railways we find a retrogression in almost every financial respect, with the exception of an increased expenditure of capital, while, on the other hand, investments in London gas companies present in all respects the most favourable features.

As it is more than probable that the Gas Light and Coke Company will eventually become the only one in London, by amalgamation with the rest, we shall, in dealing with the internal economy of the companies, only analyse its accounts, and that for the half years ending respectively on 31st of December, 1877 and 1876, by way of comparison. It appears from the revenue accounts of the Gas Light and Coke Company that the last half-year of 1877 showed sales of gas 802,720l., rental of meters 27,138l., sale of residual products 239,866l., miscellaneous 2710l., or a total receipt of 1,152,415l. against 1,180,085l. in 1876. The deficiency in 1877 was due to a diminution in the receipts for gas, and a still larger one for sale of residual products, showing a total of about 30,000l. decrease in 1877 compared with 1876. In regard to expenditure the amount charged in 1877 was 760,455l. against 771,487l., showing about 11,000l. economy in 1877 compared with the same period in 1876.

In regard to net revenue, 391,990l. accrued by the working of the company, which, with balances from last year, gave a total available fund for dividend and interest of 460,293l., which amounted at the same period in 1876 to 513,715l. After payment of interest, dividends on preference shares, and various stocks, in 1877 there was a balance of 326,537l. applicable to dividend on ordinary stock. The dividends on special stocks varied from 4 to 10 per cent., while that on the ordinary stock was 10 per cent. for the year.

Such are some of the most important financial features of the condition of the London Gas Companies for the year ended December 31, 1877, and they of course afford the basis of estimate as to the comparative status of each company in view of amalgamation. Under the present restriction imposed by the Board of Trade, and the controlling influence of the Metropolitan Board of Works, future amalgamation of all the companies promises to become a benefit rather than an evil. Of course in the present condition of London streets, burrowed with sewers, gas and water pipes, and telegraph wires, and bound on their surface by tram lines, in all directions from the City to the extremities of the metropolis, any attempt to introduce new gas or water companies would be as ridiculous as it would be impossible. The re-paving of our thoroughfares is bad enough in itself, but of course is an absolute necessity; it is certain, therefore, that the inhabitants of London would not tolerate the almost ruinous condition that would be involved in fresh competition, whether in respect to gas or water supply, no matter what benefits might follow from the introduction of new and independent sources. It only remains for the Board of Trade and the Metropolitan Board to introduce new or maintain the already existing restrictions in the interest of the ratepayers, in regard to quantity, quality, and price of the gas supplied. This being properly done, we need have no fear of any injury arising should all the London gas companies be merged into one large concern. Whatever success may eventually accrue to the application of electricity to lighting purposes, such must be very remote, and although great progress in that direction has been made during the last few years for the purposes of local illumination of large open spaces, or buildings, it cannot, under present circumstances, compete with gas for shop and domestic illumination. The gas companies have, therefore, little to fear from that source of competition, and the ratepayers but little to hope, at all events financially, for any such change.

Aug 27 '78

THE ATLANTIC CABLES.

Although the problem of deep-sea telegraphy, as regards first construction, has been long considered as solved, there remains the question of durability and maintenance, which is only slowly being answered as time gives us experience and data to determine the average durability of the various types of cable employed and the effect of different localities on them. The Atlantic cables form the most important group not only on account of their being the earliest of the deep-sea cables, but because most of the other deep-sea cables could, if absolutely necessary, be dispensed with by more circuitous routes in shallower water. We are now gaining some experience of the life of these cables, as two of the earliest laid—those of 1865 and 1866—may be considered as having terminated their existence, and the whole question of durability may be reconsidered. But although the dates of the laying and breakdown of these cables gives us an average life of about ten years, it will be seen that this need not necessarily be the limit of the life of those since laid, as improvements were introduced in their construction.

Last year an expedition for the repair of the 1865 Atlantic cable (which failed March 12, 1873), and of the 1866 cable (which failed January 13, 1877), returned after four months, having repaired one fault on the Newfoundland side and one on the Irish side in 1866 cable, and brought home a piece of cable cut out at this spot in excellent condition, but

THE GLOBE TELEGRAPH AND TRUST COMPANY (LIMITED).

The fifth ordinary general meeting of this company was held at the Cannon-street Hotel on Tuesday last, July 30, 1878, JOHN PENDER, Esq., M.P., in the chair.

The Secretary (Mr. Payton) read the notice convening the meeting. The minutes of the last meeting were read and confirmed, and the report was taken as read.

The CHAIRMAN: Gentlemen, I dare say you will observe from the report and the statement of stocks and shares that we have given you a little more information than we did before. There are two new columns which have been added, showing the respective amounts of dividends received from our investments, and the returns on cost price, which will make matters clearer to the shareholders. The investments show little change. The 2,000 Direct Cable shares alluded to in last year's report have been taken up, and are now included in our list. The average cost of our Direct shares is 10l. 13s. 11d. per share, which, looking to the market price of the day, is a source of satisfaction. The dividend, as you will observe, is quoted as 3⅓ in the List now. This means only for nine months, and not for twelve months, because the dividends for twelve months are at the rate of 5 per cent. per annum, which have been received and which are the first dividends that have been paid by the company, which was formed in 1877. A retrospect of the past two years will show that we have reason to congratulate ourselves on the improved position of Atlantic stocks, and our own shares. At this time, in 1876, Anglos stood at 57⅞, and in 1877 at 58½, now they are at 64. These calculations were made at the end of our financial year, namely, July 15th. They are a little lower to-day, but I am speaking of the period when your accounts were made up. They are somewhat lower since, on account of the failure to repair the 1866 cable. In 1876 Directs stood at 7⅞, in 1877 at 13; they are now about 14. The increase in value in two years has been something like 6 per cent. in the case of the Anglos, and 30 per cent. in the case of the Directs. To put this in plain results, we may say that there has been a rise in Anglo stock equivalent to 420,000l. on the whole of the capital, and 67,000l. on the stock held by the Globe, and of 390,000l. in Direct shares taken as a whole, or 37,000l. on the Direct shares held by the Globe. This is attributable to the action of this company in bringing about a working arrangement between the Atlantic companies instead of leaving them to do, by hostile competition, private rebates, and commissions, as much injury as possible to each other. Our own shares have participated in the improvement. A little calculation shows that the total value of our stocks and shares on the 15th July, 1877, was about 2,260,700l., and at present quotations about 2,398,000l., or an increase of 137,300l., or say six per cent. all round, which is an important advance on the year. The value of our own shares, taken at the price of the day, is 2,541,000l., or a value over the stocks and shares we hold in trust of about six per cent. The difference arises from the appreciation of shareholders of the security given by this company in spreading the risks by investment in various companies. Our shares in combination, that is preference and ordinary, taken together, represent a market value of 85 per cent., that is, taking the preferences at 11 and the ordinaries at 5½ and this is a higher quotation than any other telegraph company now possesses, the submarine excepted. Shareholders who have exchanged for Globe shares have nothing, therefore, to regret, but they exchanged. As regards the revenue account, our receipts, as mentioned in the report, have been augmented by a larger dividend from the Anglo, namely, 4½ this year, as against 3¾ last year, and the first three dividends of the Direct Company, and that enables us to recommend a dividend of 4 per cent. on the ordinary shares, and to carry forward a balance. Our payments are altogether 100l. in excess of last year, but this arises from our having to increase our staff, owing to the large increase in the number of shareholders, which, from 2,700 in 1874, has grown to 4,500 in 1878. This large increase and our system of quarterly dividends entail extra expense. The item of interest on loans was incurred in respect of the carrying forward of the 2,000 direct shares. It would have been larger had it appeared in the form of dividends on shares issued for the Directs, for we were able to borrow at a less rate than the dividend we are paying. The same observation applies to the loan of 26,000l. which appears in the balance-sheet. That amount is borrowed at bank rate, and it suits us better to wait until our shares reach such a price as will enable us to issue them without any, or, at all events, very little discount. For the next year we have reason to anticipate our revenue with increase. The advance to the River Plate Company in the balance-sheet of 236l. 10s. will be repaid in a short time. It was a sum we advanced, in common with two other companies, to enable a commission to be sent to Brazil to look into the affairs of the River Plate Company. The mission has been successful, and the prospects of that company are such now, that the item of Globe-holding, although small, will, I believe, be very profitable. The item "interest in suspense," 1,796l. 9s. 11d., has reference to a former purchase of direct shares. We had to pay interest at the rate of four per cent. per annum until we took them up; but there is a dividend payable on shares as soon as dissentient shareholders are settled with by the liquidation of the Old Direct Company, which will extinguish that item. Now, gentlemen, I have given you these particulars because they immediately bear on the value of your property and also your balance-sheet. I do it also for the reason that there are many people who do not understand the position of the Globe Company or the peculiar nature of their property. Some people suppose, because the Globe shares are at a discount, that so much loss has occurred to the shareholders; but in the remarks that I have made you will observe that any man who exchanged his shares in any other telegraph company into the Globe as they stand to-day, will find them of greater value than if they had remained in the company from which he had transferred them. Therefore, the satisfaction is in two ways; you will observe that our shareholders have doubled themselves in number, showing that there is increased confidence in the investment. That there should be increased confidence there ought to be no doubt, because you have all the different telegraph companies contributing, and, consequently, if one is a defaulter, another is paying something extra, and, therefore, in that way you get a fair average; for instance, in our own case, Direct shares have paid nothing until now. The business of the Indo-European Company was interrupted on account of the war for several months, and the consequence was that there was no dividend paid, but they are now working satisfactorily, and they have entered into an engagement with the Eastern Telegraph Company, which will enable them, I hope, in the future to pay a steady and a very fair dividend. As you are aware, this company entirely depends upon the successful working of those companies in which we hold shares. We may be said to be very large shareholders in all these companies. It is the business of the Globe so far to look after their dividends as to see that each company is working up to the point in economy and efficiency in every other way as to ensure to the shareholders a fair and steady dividend [hear, hear]. The more that these companies progress, of course the more the Globe must increase in their dividends. I think now that peace may be said to be established—at least, I hope it is established, and established upon a permanent basis—trade will be emancipated from the extreme depression which has prevailed for so many months, I might almost say years; and with the revival of trade you may depend upon it that there is no Telegraph Company which will not participate in the increase of receipts [applause]. With these remarks, gentlemen, I beg to move the following resolution:—"That the report and accounts of the directors for the year ending the 15th July, 1878, submitted to this meeting, be, and they are hereby received and adopted, and that in accordance with the recommendation of the Board the following dividends be now declared, viz., three shillings per share on the preference shares, making, with previous quarterly payments, 6 per cent. for the year ending 15th July, 1878, and two shillings per share on the ordinary shares, making, with previous quarterly distributions, 4 per cent. per annum for the year ending the same date."

SIR DANIEL GOOCH, Bart., M.P.: I have much pleasure in seconding that motion.

The CHAIRMAN: Before I put the resolution, if any shareholder has any question to ask I shall be very happy to answer it.

Mr. NEWTON: I should like to ask for some information with reference to the Anglo Company, particularly as to the condition of the cable. Is there any intention of issuing the remaining shares of this company? I think, sir, as you show such a great advantage to the holders of the Globe property, you would be doing well to telegraph property generally, and to the Globe especially, if you can increase the holding of telegraph property by exchanging farther, and embarking more of your capital in the various companies.

The CHAIRMAN: I think it would not be quite wise on my part if I were to anticipate the statement of the Chairman of the Anglo-American Company, whose meeting is to be held on Friday. I can only say that, so far as I have heard, the core of the cable, that is, the gutta-percha, is now as perfect as on the day it was first put down. But, as I have said, I have no doubt a full statement will be made at that meeting, but I have that faith and belief in scientific progress that I think the difficulties which we begin to realise in this new property of cables are likely to be overcome. I know there are gentlemen present who believe that an Atlantic cable may be made to live for all time. I only wish that proposition could be fairly established, because if it were fairly established the advantage to telegraph companies would be something enormous. However, we will not anticipate what is to be said on Friday, but I trust that science will be able to effect what we hope. As to the issue of further stock, the principle of the Globe is to exchange the shares of the Globe with existing companies, if they can be exchanged at a price which will be satisfactory to the Globe. Therefore I think, although we may consider our books closed at the present time, if we find anything like pressure, or anything like applications of such magnitude from outside people as to induce us to make a further issue, the board will of course consider it. As it is part of the principle of the Globe, I should think it would very likely adopt it; in the meantime we do not entertain any proposition just for the moment.

The CHAIRMAN then put the resolution, which was carried unanimously.

The CHAIRMAN: The next resolution I have to put to the meeting is—"That William Ford, Esq., be and is hereby re-elected a director of the company."

SIR JAMES ANDERSON: I have great pleasure in seconding the motion.

The motion was put, and carried unanimously.

The CHAIRMAN: The next resolution I have to put before you is—"That Sir Daniel Gooch, Bart., M.P., be and is hereby re-elected a director of this company."

Mr. FORD: I have the honour of seconding the motion.

The motion was put, and carried unanimously.

The CHAIRMAN: The next resolution will be moved by Mr. Griffiths.

Mr. GRIFFITHS: Mr. Chairman and gentlemen, I rise with much pleasure to tender our thanks to the directors for their able management during the past year. The unanimity with which you received the report, I think, is a convincing proof that you are satisfied therewith. It is a remarkable statement that our Chairman has made, that the number of shareholders has increased to such a large extent as from 2,700 to upwards of 4,000. Considering that the growth of the society is so large, the fact that so few members are present shows that the report gives satisfaction to the shareholders and public generally. I have glanced over the list of our shareholders, and it certainly contains the names of persons of great influence in all parts of the United Kingdom; and, also, persons of great talent and great scientific skill who are able to judge for themselves. Looking to the facts, I think we have also further cause for congratulation. Last year, the dividend had fallen off on the ordinary shares from the sum of 3s. to 2s., 1s. 9d., and even to 1s. 6d. It is a great thing that peace has been restored, and war is at an end, and that the dividend should again rise to 2s. This, I think, must be a cause of congratulation to us all. On the other hand, we must remember that the cause of the dividend falling off was not due to any fault of our directors, but rather to that spirit of warfare and antagonism which sprung up between the Direct Company and the Anglo-American Company. The warfare was forced on the directors of the Anglo-American by their own company; it was considered necessary. Therefore, although the dividends did fall off, I think the directors of that company were to be commended for the policy they adopted and for the results which have been attained. For those results I believe we are to a great extent indebted to our chairman, Mr. Pender [hear, hear]; he certainly showed great skill in a most difficult crisis. It is a great satisfaction to us that peace is now restored, and our dividend rising again. There is one subject more of regret which our report discloses, and that is that Mr. Cyrus Field has ceased to be a director. The name of Field is so well known in different circles—in political, legislative, and scientific circles, and especially in circles connected with the electric telegraph—it is a cause of regret that he no longer forms a member of our board. You are all probably aware that it is to the family of the Fields that the Anglo-American Company owes its origin, both in the suggestion, and the perseverance, and moral courage which, after so many phases, succeeded in uniting together the two continents of Europe and America. Good men and true men are scarce. Our company is of such large dimensions, and has grown to such magnitude, and its shareholders are so numerous, that we cannot afford to lose any good director. I should be rather in favour of increasing our number of directors, if we could find any equally good. But I think we should pay that debt of gratitude which is due to those gentlemen who are at present in office. They, no doubt, have a stupendous concern to manage, and their management has been distinguished by great skill and considerable success. The name of Pender must give confidence to all persons connected with electric telegraphs; the name of Massey, so well-known in political circles, must also increase our importance; while the name of Sir Daniel Gooch, a host in himself, well-known in the railway world, must add to the *prestige* and strength of our company. It is therefore with the greatest pleasure that I move a vote of thanks to the directors for their able management during the past year. As justice comes before generosity, I think we should also consider the remuneration which is due to them. We have gentlemen of great talent, great skill, and great reputation devoting themselves to our service. In times past we readily voted the sum of 1,000l. per annum. I think, under the circumstances, considering the progress of the company, the success which has attended their management, and their reputation with the public, that the least we can do on the present occasion is to vote them 1,500l. for their services. It is but a trifle when you consider the magnitude of our capital, nominal or real; it will not make any appreciable difference in the shareholders' dividends—500l. out of so many thousands is a mere drop in the ocean. On these grounds I have great pleasure in moving, "That the thanks of this meeting be given to the directors for their able management of the company's affairs during the past year, and recommend that the directors henceforth receive the sum of 1,500l. per annum.

Mr. LLOYD: I beg leave to second that motion.

Mr. BURGE: I beg leave to support the resolution. I am the holder of a great many thousand preference shares. I look upon this as the time when some further recompense should be given to the directors in recognition of their services. A year ago a great attack was made upon the chairman in a paper which is stronger than fiction. I think the directors of this company had to undergo the most powerful castigation unjustly that was ever imposed. They have carried us through a period of great trial and difficulty. I believe they have done a great deal to rescue from a large loss a very valuable property in the Atlantic. I think when we the shareholders of this company entrust to them capital to the extent of two millions-and-a-half, they have a very serious charge, and I do not understand how we can expect gentlemen of their reputation and position to undertake the responsibility of looking after that upon the same terms as those upon which they started, because they represent each shareholder. If we were private shareholders, considering the various companies that are in existence, we should take a very great deal of time to see that the company's affairs were well managed. I do not understand how our directors can be expected to look after the business of twelve or thirteen different companies unless they are a little more fairly remunerated. I think the trouble and difficulty which they have had to encounter, and the malignity with which they have been attacked in the Press, should cause us to recognise their value. I think, if we have an income of 150,000l. or 160,000l. a year dependent upon their exertions, that 1,500l. a year is not too much to give them in return. I have the greatest possible pleasure in supporting the resolution moved by Mr. Griffiths. I do not know one of the directors personally, but I cannot help thinking that we should be only doing justice to men who are looking after our interests to such an extent by remunerating them a little more handsomely [hear, hear].

Mr. GRIFFITHS then put the resolution, which was carried unanimously.

The CHAIRMAN: Gentlemen, I beg to thank you on behalf of my co-directors and myself for this renewed proof of your confidence. I dare say it will be in the recollection of some of the gentlemen in this room that shortly after this company was formed, I think about a couple of years, there was a motion made that the directors' remuneration should be 2,000l. I do not remember the name of the gentleman who made it, but I, on the part of my friends sitting around me, declined any increase upon the 1,000l. until we had got the company into a thoroughly satisfactory position. I think we are placed before you to-day in a very satisfactory position [hear, hear]. What one of the gentlemen who has just spoken said, that we have been very much maligned, is quite true; but, as long as men feel that they are doing their duty, and can show good results from their action, they are in the proud position of being able to treat with the most perfect contempt all attacks that may be made upon them, from whatever quarter they may come [hear, hear, and applause]. But, gentlemen, if we have the confidence of the body of shareholders (and we will only hold that confidence as long as we can show results) you may depend upon it your interests will be protected, and those who make those attacks which have been referred to, will in the end feel that they are rather doing us good instead of harm [hear, hear]. With these remarks I beg to thank you very much for the confidence you have reposed in us to-day. It is a very unusual thing indeed for a meeting to be so unanimous as you have been in increasing the directors' fees. I do not think that at any meeting which I have ever attended I have seen so much unanimity as I have to-day. You may depend upon it, it will have its proper effect upon the directors [applause].

Mr. NEWTON: I do not interpose, because I am a preference shareholder. I think that the resolution which has just been carried should have been proposed by an ordinary shareholder, seconded by an ordinary shareholder, and supported by an ordinary shareholder. I beg to say that I thoroughly oppose it. I did not vote against it, because I am only a preference shareholder. I have great pleasure in moving, "That William Newmarch, Esq., F.R.S., and John George Griffiths, Esq., be and are hereby re-elected the auditors of this company for the current year, at a remuneration of thirty guineas."

The CHAIRMAN: I always like, as far as one's knowledge goes, to give the shareholders the full benefit of my information. I may mention to Mr. Newton that he has a perfect right, as a preference shareholder in this company, to move or vote as he pleases. There is another company, at a meeting of which he made a motion, as he is aware, in which he was out of order; but, when this company was dealt with, it was thought better to amend the articles of association, so as to enable the preference shareholders to vote as well as the ordinary shareholders. I think, notwithstanding the remarks of Mr. Newton, who I know is a great economist, that there is not any man in this room who will more readily admit that the labourer is worthy of his hire [hear, hear]. I think that Mr. Newton will admit that during the time that we had that very hazardous battle to fight, and in which I do honestly believe that we rescued the Direct Telegraph Company from ruin, and I express my belief, although I may not have the concurrence of every gentleman in doing so, that it could be proved that the gain not only to this company, but to telegraphy as a property, was very great indeed. If Mr. Newton had been working with us, and paid at the rate we were paid, I suspect he should have had a very poor dinner to dine upon [laughter].

Mr. NEWTON: I am quite aware you gave us, the preference shareholders, the right to move and vote in this company; but I feel equally confident that I have the same right elsewhere.

The CHAIRMAN: Now, you will allow me to remind you that you are out of order.

Mr. OXENFORD: I beg leave to second the motion.

The motion was then put and carried unanimously.

The CHAIRMAN: I may mention that Mr. Burge, Mr. Griffiths, and Mr. Oxenford, are all ordinary shareholders.

Mr. McLAREN SMITH: May I be allowed one word of explanation? I held up my hand against that motion, and the reason I did so was this: I think this company was formed, not as a trust company, but to carry out a very different object. That I believe the directors are not doing. When once they are doing so I shall be very glad that they shall be remunerated on a more liberal scale.

The CHAIRMAN: If any gentleman holding shares in any other company will come forward, we are prepared to exchange Globe shares with him, but we cannot force that upon the other shareholders, that is not our business.

Mr. McLAREN SMITH: You may invite them.

The CHAIRMAN: We have done that periodically, and are not likely to do that again, because the expression of feeling so far has been against it. As I said before, if we find that shareholders in other companies are anxious to exchange into the Globe, we shall be glad to receive them. I think I have taken some pains to-day to show you by figures and facts that the Globe Company, with the exception of the Submarine Company, stands at the head of submarine telegraph companies as to the value of its property. I have also said that the reason of that is because it gives additional security. Beyond that I have nothing further to say. The general body of the shareholders must judge for themselves; but, if they are prepared to come into the Globe, we shall receive them with the greatest possible satisfaction. I think that that terminates the business of the meeting.

ANGLO-AMERICAN TELEGRAPH.

The report states that the total receipts from January 1 to June 30, including a balance of 3,223l. brought over from the last account, amount to 274,386l. The total expenses of the half-year, including income-tax and repair of cables, as shown by the revenue account, amount to 44,265l. The directors, under the powers conferred upon them by the articles of association, have, before declaring the net profits, set apart the sum of 75,000l. to the renewal fund, leaving a balance of 155,120l. One quarterly interim

54

OCEAN TELEGRAPH CABLES.

Speaking of relays leads us to think of cables. There is, however, not much interest to be derived from seeing cables, as nothing very new is shown. In the English department the Telegraph Construction and Maintenance Company and Mr. R. S. Newall show specimens. The former are probably the largest cable manufacturers in the world. Still a fair display is found in the French annex. The latest improvement in cable manufacture is the protection of the cable from the teredo by a brass tape wound spirally round the insulated core. M. Barron exhibits a roll of cable used in Paris after his design, which after sixteen years' service is as good as it was when first laid. The question of the life of a cable is involved, but we incline to the opinion that under favourable circumstances there is no reason why a cable should not last for 100 or 200 years.

THE JERSEY CABLE.—The fault in the Jersey Cable was localised on the 6th inst., and found to be distant about 300 yards from the Dartmouth end. The fault was a nearly complete disconnection, the cable not giving earth. This is an unusual kind of fault to occur in a gutta-percha core; though a frequent one in india-rubber cables. It is anticipated that the cable will very shortly be through again to Jersey.

A SHORT cable from Darien to Doboy Island, the port for Darien, has been laid and opened for business.

A WEDDING was recently consummated by telegraph between a bride in Ohio and a bridegroom in Colorado. The lady took the next train for Colorado.

DR. MUIRHEAD, who has been delayed in his work by repeated teredo interruptions on the cable, succeeded in completing the duplexing of the Madras to Penang cable in a few hours after it was placed at his disposal. He will return home early in January.

A vote of thanks was passed to the Chairman and directors for their satisfactory conduct of the affairs of the Company, and the meeting then separated.

MEDITERRANEAN EXTENSION TELEGRAPH COMPANY (LIMITED).

The 42nd ordinary general meeting of the shareholders in the above company was held on Wednesday, the 21st inst., at the City Terminus Hotel, Cannon-street, under the presidency of Sir James Carmichael, Bart., chairman of the board.

The report of the directors for the half year ending the 30th of June stated that there had been a sensible improvement over the working of the previous six months. They recommended the payment of the usual 8 per cent. dividend on the preference shares, less income-tax, and of 3 per cent. on the ordinary stock, free of income-tax, payable on and after the 1st prox., carrying 471l. 13s. 4d. to reserve fund.

The CHAIRMAN, in moving the adoption of the report and accounts, stated the report informed them of everything which had occurred since the last meeting. With regard to the cable which was injured, it was the old original cable—the Alga-Grande cable. He thought it was injured about seventeen or eighteen miles from the Sicilian coast. There was no difficulty in repairing it; but, unfortunately, the steamers which belonged to the Eastern Company, of which they hoped to avail themselves, had been very much employed lately. In the meantime their traffic went by other cables. They did not lose anything by this interruption, but it was a question of delay. They hoped in a few weeks to get a steamer, when no doubt the cable would not take more than two or three days to repair. It had been raised, and, considering the time it had been down, he did not think it was in very bad condition. With regard to the reserve fund, and the conflicting claims of the ordinary and preference shareholders, they would recollect that at the last meeting a wish was expressed by the proprietors that they should take counsel's opinion as to the exact position of that fund, or whether it belonged to the ordinary or preference shareholders, or both classes. Accordingly, their solicitor drew a case, which was shown to counsel, going through the whole matter from the beginning. This was laid before Mr. Kaye, Q.C., one of the most eminent members of the Chancery bar, and he had given his opinion on the case presented, that the ordinary and preference shareholders would be entitled to divide the assets, including the reserve fund, *pari passu*. In this opinion the solicitor of the company coincided. It was clear, therefore, from this that the reserve fund belonged to both classes. At the same time, as he had explained before, it was a fund for the maintenance of the cable, and they drew on it from time to time for the renewal of their line, which, therefore, benefited both classes. He concluded by moving the resolution.

Mr. FIELD having formally seconded the motion,

Mr. ROBINSON congratulated the meeting on the improvement in the receipts, as compared with the corresponding period of the previous year, and on the increase in the reserve fund. He spoke of the advantages to the ordinary shareholders of amalgamating the undertaking with the Eastern Extension Telegraph Company.

Mr. JOHN GRIFFITH acquiesced in the last remarks of Mr. Robinson; and, in the interest of the ordinary shareholders, he urged on the directors the necessity of coming to some arrangement with the Eastern Company.

Mr. VEARS thought a too gloomy view had been taken of the position of the company's affairs.

Another Shareholder advocated the policy of amalgamating the undertaking with some larger company.

The CHAIRMAN, in reply, at the close of the discussion, said he was certainly of opinion that the ordinary expenses of repairing their cable ought to come out of the half year's revenue. He could hardly anticipate what the cost of the present repair would be. Directly he heard of Cyprus coming under the protection of the British Government, he put himself in communication with the Treasury to see whether anything could be done for the extension of their system in the Mediterranean. He believed that nothing definite had been decided on as to who should have the telegraphic communication between Alexandria and Cyprus. As to the question of the amalgamation, they were always open, and since their last meeting he had been in communication with a proprietor in this company, who was also a proprietor and the legal adviser of the Eastern Extension, to see if anything could be done, and that gentleman had promised to consult with this company's legal adviser. He did not know, however, what the Eastern would do. He had heard that the company did not care to take them; but he quite agreed that it would be to the advantage of the company, and wise of them, to take them. When their solicitor returned, he would consult with him as to further communicating with Mr. Kaye, but he thought they might take it for granted that the result would be the same.

The report was then unanimously adopted, the dividends were declared, and the retiring directors and auditors were re-elected.

The meeting separated after passing a vote of thanks to the chairman and directors.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).

The fourteenth ordinary general meeting of the shareholders in this company was held on Monday, the 19th inst., at the offices, No. 61, Old Broad-street, under the presidency of Mr. Thomas Hughes, Q.C.

The report of the directors stated that for the half year ending the 30th of June the gross receipts had been 18,278l. and the gross expenditure 15,920l., leaving 2,358l. to the credit of revenue account. The unusually large expenditure arose entirely from the cost of the repair of the Cienfuegos-Santiago section of the original cable, amounting to 12,602l., the ordinary expenses amounting to 3,317l., being rather less than usual. They considered that they were warranted in charging 5,575l. of the cost of the repairs to the reserve fund, and this sum, added to the balance of the revenue account, would admit, after providing for the preference dividend, of a dividend on the ordinary shares at the rate of 6 per cent. per annum.

The CHAIRMAN, in moving the adoption of the report, said the shareholders would, of course, expect to hear something about the repair of the cable during the half year, and he thought it would be interesting to them to know something of its history, that they might judge of its probable future, and of the consequent chances of prosperity to the company. The cable, then, was laid in April, 1870, and as early as October, 1873, the first interruption occurred. It was a very serious matter, and he thought that the comparison of the state of things then and now would be very encouraging to the shareholders. On the first occasion the interruption lasted over six months—up to April, 1874, during the whole of which the cable remained dumb, resulting in a total loss of traffic, as the company then had only a single cable. The cost of the repair, too, was over 20,000l. In consequence of that interruption, and of what occurred at the time, it was resolved to lay a second cable, and the results of that policy were seen on the present occasion. The cable was cut and landed at Cienfuegos in April, 1875, and had been duplicated all the way to Santiago; and by this policy the whole of their traffic had been saved. They had lost nothing at all in the way of business through the late interruption. Their officer on the spot had executed the repairs in a most satisfactory manner, and the whole cost had been 12,602l. The work, too, was executed in forty-five days instead of six months. They were able to do this in consequence of obtaining the services of a vessel on the spot—he referred to the repairing ship belonging to the West India Company; and Mr. Keith had conducted the operations on board that vessel entirely to the satisfaction of the board, and, he thought, in a manner which would prove thoroughly satisfactory to the company in the future. He thought they might now consider that they had their duplicate cable in thoroughly good order. As referred to, it was clear that this species of property could not be regarded as permanent—the "life" of a cable could not be reckoned to be anything like perpetual. In fact, experience hitherto had been that the "life" of a cable did not exceed, even if it came up to, ten years, and he had no doubt that all who were interested in such matters were aware that two of the Atlantic cables had been abandoned, and he did not believe that the "life" of those cables would be found to average ten years. The conclusion from this would be that it was necessary for every company desiring to conduct its business prudently to lay by a considerable portion of its earnings to a reserve fund to meet these contingencies. This had been the policy of the Cuba board from the first, and the proposal that day to pay a smaller dividend than they had lately paid arose entirely from the desire of the board to keep the reserve fund in an entirely satisfactory position. In their view it would not be in such a satisfactory position as they could desire it till they had sufficient reserve to enable them, if it became necessary, as it might, to lay a new cable from one end to another. Till this happy result was obtained, the Board would not cease to urge on the shareholders the necessity of providing a reserve fund of an adequate amount. They had received several communications from shareholders acquiescing in the prudent course suggested by the Board, and expressing their willingness to accept the temporary diminution of dividend recommended to-day. After reading one of these letters, the Chairman, in continuing, said he was very glad to see so many of the shareholders taking an interest in the company's affairs, as their doing so strengthened the directors' hands. He might state that they now had over 400 shareholders, whereas when they started he believed that they had very little over 100. He thought this was probably an evidence of the increasing confidence in the company. As compared with the corresponding half year of 1877, their receipts showed a falling off from 19,500l. to 18,300l.; but the Board saw no reason to regard this as any sign of a permanent depreciation. They considered that the diminution was accounted for to a very great extent by the large increase of the tariff charged by the West India Company, which had had the effect not of reducing the number of messages; but it had had the great effect of lessening the number of words of the individual message, and the consequence was the considerable reduction he had mentioned. Mr. Keith, he was glad to say—for that gentleman was an exceedingly competent officer—was thoroughly satisfied with the state of all the cables. That gentleman had just completed a very important work for the company's neighbour, the International Ocean Company, whose cables had been broken. An application was made to them for the services of Mr. Keith to take the control of this repair, and they were very glad to allow this. It gave their officer more experience in a very difficult part of the ocean for laying cables. It also strengthened the good understanding between the company and the International Ocean Company, and also allowed the latter to test and to prove the value of their repairing ship. He concluded by moving the resolution for the adoption of the report, observing that he hoped the shareholders would approve the wisdom of the dividend being only at the rate of 6 per cent. on the ordinary capital.

Mr. N. BANNATYNE, one of the shareholders, formally seconded the motion.

Mr. NEWTON asked for some information as to the investments, and the probable effect on the company of the new traffic to South America. Was their system, too, entirely duplicated? He could not believe, as he had heard stated at another company's meeting, that this company's cable was laid "in circles."

Mr. GRIFFITH said he appreciated the value of caution, but in the present circumstances and condition of the company, as referred to by the Chairman, he thought they were erring on the side of too great caution in the dividend recommended that day. He admitted that any temporary fault should be charged to the half-year's revenue, but the late interruption and consequent repairs arose from their cable being laid, not in circles, but badly, and having got in circles afterwards. He thought the dividend might be increased from the reserve fund, which he thought would increase the value of their shares. The preference share had risen in an extraordinary manner, while the ordinary shares had not risen. This fact, he thought, proved that the public considered that the ordinary shareholders had burdens thrown on them which were hardly equitable.

After some remarks from Messrs. QUILTER and HOOPER,

The CHAIRMAN, in reply, said, as to the first question asked, they had 10,000l. deposited with the Chartered Bank of Australia, and a similar amount with the Bank of New Zealand, and 4,000l. in Six per Cent. Debentures of the West India and Panama Company, which had been handed over to them as a compromise of the cross claims between the two companies. Their system was practically duplicated throughout the submarine portion which belonged to the company, was duplicate over the whole system, from Cienfuegos to Santiago, which was more than four-fifths of the system, and which included all the deep water. From Batabano to Cienfuegos their own submarine cable was single, but the Government lines were all running now. Their cable was certainly not laid in circles, but as direct as possible between the two points. All the navigable portions of the cable, as originally laid, had also now been cut out. He did not think there was much chance of the southern extension being made within any short time, but when it was it would add considerably to their traffic. He did not think it would be judicious to trench farther than they proposed on the reserve fund—to pay the dividend of 6 per cent. they were going to charge the reserve fund with 5,575l.

The report was then unanimously adopted, and the preference dividend at the rate of 10 per cent. per annum, and the dividend on the ordinary shares at the rate of 6 per cent., were declared.

The retiring director, M. Joaquin de Mancha, and the auditor, Mr. James Cowan, were re-elected, and a vote of thanks to the chairman and directors brought the proceedings to a close.

An Improved Method of Carrying Underground Telegraph and Telephone Lines.

One of the most practical steps towards meeting the requirements of underground telegraphy, has been taken by the National Underground Electric Company, whose pipe line system for carrying wires and cables for telegraphic and telephonic purposes we describe and illustrate in the following.

The plan of this organization is novel, in that it does not propose to lay and operate telegraph or telephone lines of its own, but simply to furnish the existing telegraph and telephone companies with their underground pipe line, capable of accommodating any desired number of wires, and to keep and maintain the same in good working condition, for a term of years, under properly executed leases or contracts, the company expecting to derive its revenues from a system of rental based upon a certain schedule of charges per mile of wire. This plan is free from the impracticable features of some of the methods of underground telegraphy that have lately been proposed, in that it does not bring its advocates into conflict as business rivals with the existing telegraph and telephone companies, and is not committed to the use of any particular mode of construction, preparing and insulating wires or cables, but, on the contrary, proposes to accommodate all comers with the facilities for conveying their lines underground.

We have thought this preliminary explanation of the nature and objects of the company necessary, for the reason that we, as well doubtless as many others, have at first been misled by the name of the organization into the belief that it was an underground telegraph company. From the foregoing remarks, our readers will understand that it is a pipe line company for affording telegraph and telephone companies facilities for carrying their lines underground. With these explanations, we proceed with the description of the special plans of the company, which are protected by several letters-patent of the United States.

The method of constructing the pipe line is as follows: Cylindrical pipes of terra-cotta are made, perforated lengthwise with numerous small holes, forming continuous tubes, covered with a vitrified glazing on the outer and inner surfaces. The pipes are designed to be laid end to end underground, and firmly cemented together (this being easily accomplished, the pipes having a bell or socket on one end of each), thus making a continuous line of terra-cotta pipes, through which the wires or cables are run. The construction of these pipes is shown in Fig. 1. These are laid in sections, and at convenient distances excavations are made in the ground and carefully bricked and cemented up, thus making an underground water-proof chamber between each section (such sections being of any desired length), by which system of underground chambers, in connection with the conduits, the wires can be withdrawn and replaced at will, and the number decreased or increased as required for any purpose, without digging up the streets, which has been strongly urged as an objection to the underground telegraph in cities. As the pipes are laid, small wires are placed in the holes, all the wires in each section ending in the sunken chambers. The design of this is to enable the workmen in the chambers to draw the cable or bundle of wires through the perforated blocks, by means of a reel, as fast as needed.

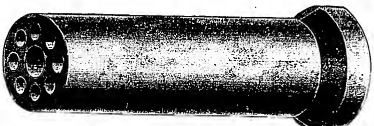

Fig. 1.—Perforated Terra-Cotta Pipe for Underground Telegraphy.

Fig. 2 is a section showing the pipe line in position, and the method of drawing the wires through the same.

When a section is laid and ready for use, a rubber pipe or hose is drawn through the holes in the pipes, and in this the insulated cable is placed, thus encasing it in a vitrified terra-cotta pipe, lined with rubber—a threefold protection against the dampness of the earth. The different kinds of wires may be completely separated, while a small pipe may carry a thousand wires without inconvenience. Branch lines will be laid to offices and buildings, by pipes laid under the pavements, from the chambers at the ends of the sections. These chambers are designed to be covered when not in use, and will not interfere with street traffic. The company claim that their system is much cheaper than any hitherto proposed, and it certainly has the merit of removing the wires from the streets and house tops, and at the same time preventing the continual tearing up of the roadway to lay new cables or repair old ones, which is a grave objection in other systems. By this system, there is no danger of our telegraph, telephone and other wires being broken down and communication interrupted, as was the case during the last winter on several occasions, and for days, thus entailing great loss on the business community.

The company claim for their pipe line system a number of advantages, of which the more prominent are named below: Efficient protection against ground moisture, which would affect the insulation of the line wires; the great facility which it affords for handling the wires or cables, either for introducing new ones or withdrawing or repairing the old ones; the complete avoidance of the objection of disturbing and tearing up streets and pavements to meet the demands for additional wires after the line is once laid; the fact that they propose to accommodate all comers with facilities of an underground conduit for all kinds of wires and cables; and the provision of separate chambers for wires of different lines.

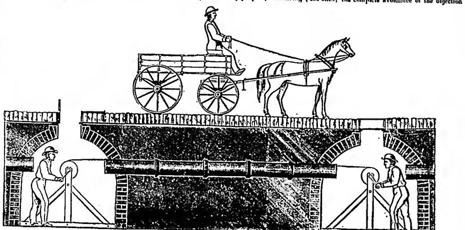

Fig. 2.—Section of Pipe, with Testing Stations, Showing Manner of Inserting Wires. These Testing Stations may be any Required Distance Apart.

From the above description, the company's system would appear to be as simple and efficient as any that could well be devised, and it certainly answers many of the objections that have been advanced against the underground telegraph in cities. When once laid down in the street, it is there for good, and capable of accommodating any reasonable increase in the number of wires that will be likely to occur for years. The material of the pipes is practically indestructible, which cannot be said of lead or iron under the same circumstances; and the means provided for manipulating the

and there is every reason to be proud of the success obtained. Similar experiments were made on the same day by different eclipse parties, among them that from the Smithsonian Institution, composed of Professor Newcombe, of Washington; Professor Young, of Princeton; Professor Langley, of the Alleghany Observatory, and others. According to telegraphic despatches the success was complete, but we must wait for further details before we can give the exact results.

STUDENTS' COLUMNS.

FRICTIONAL ELECTRICITY.—A NEW ELECTROSCOPE.

The form of electroscope now described was devised by me a few months ago.

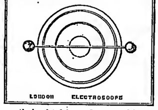
It seems remarkable that frictional electricity is not more studied. There is ample room in this field of electrical research for new discoveries.

The following is a brief outline of the construction of the instrument illustrated:—

The diagram is a plan of the electroscope. The stand of the instrument may be made of wood, brass, tin, or even stout card board. It is essential, however, that the stand of the instrument be weighty.

The arrangement looks neatest, as shown in the diagram, viz., circular. Fixed to the centre of the stand is a thick stick of sealing-wax, or a glass leg coated with shellac. This leg, as a matter of course, is at right angles to the plane of the stand of the electroscope. The length of this insulator need not be more than eight or ten inches. The dotted circle shown in the centre of the diagram, illustrates the position occupied by the insulated support. To the top of this support is affixed by sealing-wax a short pointed wire about one inch long.

The upper portion of this electroscope is made to rotate.



Resting on the insulated leg, and supported by a "cap," is a rod of light, dry, and straight wood. This part of the electroscope need not be any stouter than an ordinary penholder, the object being to have it as light as possible, attached to the ends of the rod in a pair of round balls.

The introduction of balls on electroscopes is to me a new feature. I have never seen such an arrangement mentioned in any of the text-books that fall into the hands of electrical students. Therefore, I have thought fit to name the electroscope as seen in the diagram.

Having given a general outline of the construction of the instrument, I will deal with its

Action.

a. If a positive (+) glass rod be brought *near* one of the balls, the electricities on the rotating part of the electroscope immediately separate; the ball then moves towards the + rod. This at once induces polarity in the electroscope.

b. Carry in front of the ball the + rod, and you will cause the electroscope to rotate on its axis many times. This is caused by the — E following the + E.

c. Let the moving portion of the electroscope come into contact with the + rod, and a new state of things is the result. The electroscope now no longer follows the path described by the + rod, but appears at once stationary. If the + rod be moved at this moment from off the rotating piece of wood, and then brought near to one of the balls, the moving system goes backward. This is owing to the + rod combining with the — E that resided on the electroscope, consequently repulsion at once occurs.

d. Laying down the + rod when the motion of the electroscope is showing the dual force of electrity, and taking up a rod of brass, or any conducting substance, bringing the conductor near one of the balls of the electroscope, attraction is manifested.

e. Let the instrument return to a neutral state. Excite your rod and bring it near one of the balls. Keep the ball revolving after the + rod, taking care that the balls *never* come in contact with the rod. By so doing, the moving portion will soon show signs of independency to the + glass rod. When the electroscope ceases to follow after the rod at this stage of action, on bringing the rod *near* one of the balls at the moment, they wander backwards as before, yet contact has never taken place.

A dielectric may be suspended and carried in front of the rotating balls. The same phenomena in this case takes place. Induction here turns a corner, or is exerted in a curved line which cannot be accounted for in any other way than supposing the air between the glass rod, and the balls serve as a medium for the transmission of the rod's electrical action.

With this instrument Government teachers could illustrate a great part of the frictional branch of this science at little cost.

This instrument claims to show:—

1st. Electric polarity. (See a and *b*.)

2nd. Dual force of electricity, shown by the backward motion of the balls. (See c.)

3rd. A tendency for the fluids to recombine, or a + body following after a neutral one. (See *d*.)

4th. Electric induction manifested, showing similar results to contact. (See e.)

This instrument also serves as a ladder in understanding the theory of lightning conductors. By inserting a fine-pointed wire into each ball, letting the end of such point freely into the air, the above experiments are rendered impossible.

Howorth. RALPH LOUDON.

ANGLO-AMERICAN TELEGRAPH COMPANY, LIMITED.

Proceedings of ordinary general half-yearly meeting of the Anglo-American Telegraph Company (Limited), at the Cannon-street Hotel, 2nd of August, 1878, the Right Hon. Viscount Monck in the chair.

The SECRETARY (Mr. John Grant) read the notice convening the meeting and the minutes of the last general meeting.

The CHAIRMAN: Then, gentlemen, I presume you will take the Report as read, and it becomes my duty, in conformity with the practice on such occasions, to propose to you that the Report of the Directors be received and adopted, and, in doing so, to endeavour, as briefly as I can, to give you, as our constituents, an account of our proceedings during the last half-year. Gentlemen, in reference to that subject, the principal topics, in fact the only topics which are of very much interest, are the state of your property, as regards its efficiency and preservation, the amount of income which we have received during the half-year, and the moneys which we have been obliged to pay for the receipt of that income. Well, gentlemen, with respect to the condition of the cables, one of the first paragraphs in the Report anticipates all that I have got to tell you on that subject. The three cables with which we have been operating during the past two years are in perfect order and doing our work as well as it could possibly be done. With regard to the receipts, you will see that the receipts of the last half-year are somewhat less than those of the preceding half-year; but on the other hand, they are very large receipts in comparison with what we have had in previous half-years. The second half of the financial year has always, according to our experience, been the better half; and, therefore, the 260,939*l*. receipts of the past half-year, we may confidently expect, will be increased during the approaching half-year. Now, gentlemen, I think that is a very encouraging state of things, considering the circumstances under which this income has been received. In the first instance, though we have happily got rid of hostile competition, and I see my friend opposite, who is now a very friendly member of our company instead of being chairman of an opponent company—and we are working on the most perfectly amicable terms, still we have been obliged, as you all know, to give up a certain share of our receipts to our friends and partners, the Direct Cable Company. Well, notwithstanding that, we are taking as our share what enables us to pay a substantially good dividend on our whole stock. Well, gentlemen, I am not going to weary you by repeating what you have heard for the last three or four years at every meeting of shareholders in industrial enterprises which has been held in the city of London. I will not weary you by dilating on the depression of trade that has had an injurious effect on our enterprise, as well as that of all other industrial enterprises in the country. We may hope, I trust, that some of the causes, at all events, which caused that depression have been happily removed—the dread of war, and that sort of thing; and we may hope that the pressure of that depression will, to a certain extent, before long cease, and, I hope, soon entirely disappear. And I think it is almost a matter of certainty that if we have been enabled, with the effect of that depression operating upon us, to take so good an income as we have done during last year, we shall be enabled, when that depression ceases, largely to increase our receipts. Gentlemen, I think the state of our receipts, even under the depressing circumstances to which I have alluded, bears out what I have always stated as my opinion in our dealings with the Direct Cable Company before we came to agreement. I mean that I always maintained that there was room enough in the Atlantic for both of us to make a good profit. I believe that the longer we live and the more we continue to carry on our trade, the more convinced we shall become of that fact. Therefore, I think there is no cause for depression with regard to the future. I believe we have seen the worst we are likely to meet with, and that in the future we shall improve our prospects and improve our receipts. Well, gentlemen, so much with regard to the income of our Company. Now, with regard to the cost to which we have been put. You will find on a reference to the report that the cost of working the Company for the past half-year has been 44,265*l*. Now, that includes an item of 11,000*l*. for the repair of cables, and we contributed, towards the repair of cables, t

THE PROSPECTIVE PERMANENCY OF SUBMARINE CABLES.

At the recent general meeting of the Globe Telegraph and Trust Company (Limited), which we reported in our last issue, the Chairman touched upon a point which is of the greatest moment to shareholders in submarine telegraph enterprise, and which is of scarcely less interest to electricians and telegraph engineers. "I know there are gentlemen present," said Mr. Pender, "who believe that an Atlantic cable may be made to live for all time; I only wish that proposition could be fairly established—because if it were fairly established the advantage to telegraph engineers would be something enormous. . . . I trust that science will be able to effect what we hope!"

Whilst disclaiming any pretension of adequately treating, within the limits of a single article, so large a question as that involved in the accumulated evidence bearing upon the permanency of cables, we may briefly consider, at least suggestively, whether there are any conditions under which we may reasonably conclude that a cable would remain electrically perfect for an indefinite period; and, if so, whether these conditions—mechanical, electrical, and chemical—are practically attainable with any degree of certainty, or approachable under a conjunction of favourable circumstances. It is now seventeen years since the Joint Committees of the Board of Trade and the Atlantic Telegraph Company recorded their opinion, based upon the voluminous evidence laid before them, that "the failures of the existing submarine lines had been due to causes which might have been guarded against." We have to inquire whether the same verdict is applicable, in some less degree, to recent failures—one of which, that of the 1866 Atlantic cable, would appear to be as final as that of the 1857 cable, albeit it was long de-

ferred, and is happily less overwhelmingly disastrous than the first venture of the Atlantic Company?

In regard to the first point which suggests itself, that of the chemical stability of the insulating material when submerged, we think every electrician will endorse Mr. Pender's opinion that the gutta-percha of the 1866 cable is now as perfect as on the day it was first put down. We know that in air, more especially when exposed also to light, gutta-percha absorbs oxygen and becomes partly converted into a brittle resinous substance, soluble in alcohol and in dilute alkaline solutions. Only one other chemical change, so far as we are aware, has been noticed in this material—viz., that occurring in ground containing tanno-gallic acid from oak trees or posts, and due probably to the action of a minute fungus. Signs of electrolysis, by the action of a high electromotive force, may, no doubt, be exhibited; but, even in the case of a thinly-coated wire, no appreciable alteration either of the copper or of the insulator can be produced through it, under the conditions of practice, excepting at those points where the continuity of the gutta-percha is more or less defective, or, in other words, where "faults" may be detected. In regard to submerged gutta-percha, we have the evidence of Sir S. Canning that the material was found quite perfect when the Dover-Calais cable, laid in 1851, was raised for repairs in 1859; the subsequent evidence has all been in the same direction, and we believe nothing has occurred to negative the opinion of Mr. Willoughby Smith that the gutta-percha of a submerged cable is, chemically, quite permanent, and "will last for ever."

The next point which occurs to us is the liability of the insulator to damage from the attacks of marine organisms. Amongst these, the *xylophaga*, a bivalve shell fish, and the shipworm, or *teredo*, have the worst reputation; for, although their ravages are mainly confined to the hemp which surrounds the core of cables, there is positive evidence that the former, at least, has in certain cases actually attacked the gutta-percha. We do not know of any case, however, where a failure of insulation has been traced to these organisms; their attacks being quite superficial, in the form of an elongated groove. Moreover, they do not appear to exist in any very great depth of water; so that in the case of deep-sea cables they may be altogether left out of account. The same applies also to the sun-fish, which, in one or two cases, is said to have damaged the insulation of cables by means of its caudal spines. Still, even in the case of deep-sea cables, some kind of permanent protective sheathing appears to be desirable; and we believe that special attention is now being given to this matter.

We may now consider the insulating material from an electrical point of view. And here we would most strongly insist upon the necessity, in the case of deep-sea cables at least, of the most scrupulous care to prevent any fault, however minute or incipient, being left in the cable at the period of its submersion. It may be said that scrupulous care is, at the present day, in most cases exercised; we would reply, that in our opinion it might be augmented—though perhaps at the cost of considerable delay and additional expense. We would incur this delay and expense to secure an electrically faultless cable; and, with this object in view, we would if necessary augment the ratio of the weight of insulating material to that of copper, or otherwise increase the dielectric resistance. Probably we cannot do better, under this head, than give a suggestive quotation from the Report, dated the 21st February, 1876, of Sir W. Thomson and Mr. F. J. Bramwell to the directors of the Direct United States Cable Company (Limited):

After observing that the tests applied proved the great care that had been taken in the manufacture of the cable, they state that "The laying of the cable was also conducted with the greatest care, so as to avoid leaving in it any discoverable fault of insulation, however minute. On these occasions, while engaged in the deep-sea portion of the cable, its egress was stopped on account of faults, which were very minute; two of these were hauled back and cut out on board the ship, while the third was cut out and left at the bottom. The two which were brought back have been marked with two notches and three notches respectively; these we have carefully examined, and we find in each case the fault consists of a single exceedingly small airhole through the gutta-percha—a hole so small as to be barely visible to the naked eye. On cutting down through the gutta-percha to the copper core, we found the wires composing it to be altogether undisturbed and unchanged, and to be perfectly central in the gutta-percha, thus showing conclusively that the holes were not produced mechanically by puncturing inflicted by the wires of the copper core itself. There can be no doubt from their appearance but that the holes were produced in the course of manufacture by minute quantities of air, which had been left in the compound before applying the gutta-percha."

It is easy, in the light of past experience, to trace the consequences of submerging a cable with a few even of such minute faults or weak places. After a time, the worst of these becomes considerably enlarged, the leakage through it acting to some extent as a protection to the others; the cable is raised and this fault cut out, and subsequently the next in magnitude behaves in the same way. And, though we have heard a great deal as to the certainty with which deep-sea cables can be picked up and repaired, there is, unfortunately, a considerable amount of evidence in the other direction.

Other important points are the nature of the sea-bottom and the direction and character of the surface currents. Whilst we admit that the safest locality for an electrically perfect cable is undoubtedly a level *deep* sea bottom, we can but take a gloomy view of the chances of permanency in the case of a cable laid on a sea bottom like that which prevails on some portion of the route of the direct Lisbon cable. Here we can but look wistfully towards the hydrographers and nautical men who have already rendered signal service in deep-sea telegraphy. Can they, by the exercise of the same amount of scrupulous care as is demanded of the electrician, guard us against the dangers of the rugged deep, and avoid the graceful but deadly festooning of the cable from edge to edge of the rocky chasms, of which the existence in some cases can scarcely be doubted? We can only suggest that—in the absence of surface currents, and of any necessity for "laying-to"—the most suitable cable for such a rough bed would clearly appear to be one having a specific gravity but little superior to that of water, any iron sheathing being a source of weakness rather than strength. And, in relation to this sheathing, we would submit as a logical conclusion that, in the case of an electrically-*perfect* cable, laid over a level *deep*-sea bottom, any mechanical strength above what is required to secure safety in handling and laying the cable would be superfluous, and, probably, also detrimental. And, believing, as we do, that an electrically-perfect cable is practically obtainable, we look forward to the period when the raising and repairing of deep-sea cables may be regarded as a contingency no longer to be provided for—a remedy the means for which has often brought about the disease it was to cure.

Far different is it in the case of shore-ends, and in that of cables to be laid in shallow water and even in mod[illegible] to depths. Here, we admit, experience is all in favour of heavy armour, and the necessity for raising and repairing cannot be avoided. Nor is it a necessity which, whilst our great submarine companies are provided with well-appointed repairing ships and skilled engineers, need be attended with any great anxiety or risk.

In conclusion—for our present space is limited—the conditions of absolute permanency in a cable appear to us to be summed up in two points, viz.:—1st. Perfect freedom from electrical faults; and, 2nd, a deep and level sea bottom. Both these conditions are, we think, practically attainable in the case of an Atlantic cable—excepting, of course, as regards the shore ends, the occasional failure of which would not endanger the deep-sea portion of the line. On some other routes, also, these conditions may, we have no doubt, be realised by the combined efforts of the electrician and the hydrographer. In shallow waters, a comparative permanency may be obtained through the adoption of the most effective means for raising and repairing the cable, one of the most important points being the protection and preservation of the iron sheathing. There remains, we fear, a considerable residue of cases where the second condition is unattainable, and where no aid is to be derived from this sheathing. Here the element of certainty appears to be entirely wanting, and a relative permanency is attainable only by a conjunction of fortunate accidents. Yet even here, under the almost prohibitive condition of a deep and rocky sea-bottom, there are important problems to be solved; and possibly much may be done by the association of the hydrographer and the telegraph engineer.

Anglo-American Telegraphy.

The subject of Anglo-American telegraphy is again occupying the attention of some of our contemporaries, who appear to think that above all things it is necessary that English shareholders should provide, at their own cost, the blessing of cheap telegraphy. It is even hinted that it is not improbable that a new company may be started in New York "to be brought out here;" in other words, that the formation of another enterprise, such as the Direct United States cable, may be attempted. A council of "traders and merchants of New York" will probably move that "cheap telegraphy would be of advantage to the merchants and traders of this city, that American capitalists have not hitherto invested any money in these undertakings, and do not intend to do so, resolve, therefore, that English shareholders be afforded an opportunity of doing for us what we decline to do for ourselves." When any such proposal is submitted to British investors they will probably remember the history of the Direct United States Cable Company formed about three or four years ago, for providing precisely the same blessings and under the same kind recommendations, and that that company was only saved from absolute ruin by being taken over by the company whose rival it was intended to be. After great disappointment and delay the cable of the Direct Company was laid, but the shareholders never received any dividend, and the majority of the shares were disposed of at a discount of about 50 per cent. There are large claims still outstanding against the company on the part of contractors and others, and it will be some time before the shareholders, even under the present arrangement, will receive any return on their money. What reasonable pretexts or prospects can exist for the formation of another company for carrying out this "desirable" object those who invested their money in the Direct Company will have peculiarly favorable data for judging.—*The Railway News.*

We learn from the *Journal of the Telegraph* that a project is on foot to connect Cape San Antonio, Cuba, with Guatemala by submarine telegraph, and that concessions have already been obtained in Honduras and Salvador.

The short cables from Newark to Heligoland and from Trinidad to Demerara are interrupted. Para is reconnected to Pernambuco on the south, but no attempt has of late been made to restore communication with Cayenne and Demerara on the north. Feb 79

The Cape Cable.—The Eastern Telegraph Company have offered the Government the 1,400 miles of Australian cable now shipped, but the Government refused the guarantee against accident which the company stipulated for, and the negotiations were broken off. The India Rubber Company have offered to make and lay a cable within this year.

Public complaint has been made of the errors in the names of the killed and wounded in the Zulu war, as telegraphed from St. Vincent.

Apropos of the Cape Cable, our French contemporary *L'Electricite* calls for cable communication between France and her colonies of Senegal and New Caledonia.

Oct 66

Anglo-American Telegraph.

The announcement made a few days since to the effect that no further attempt will be made this year to raise the 1865 cable, which, upon being grappled, was found to be unsatisfactory, will probably have a useful deterrent effect in damping the ardor of those who are so eager to witness an active competition of ocean telegraphy. If the 1865 cable be as unsatisfactory as it is reported to be, it is obvious that any new company possessing only one cable cannot afford to indulge the public with the luxury of cheap telegrams, as the amount of reserve which must be set aside to provide for renewals of cable would make very large inroads upon net profits. A cable which costs something like £1,000,000 before it is laid across the Atlantic, and which lasts only ten years, will require nearly 10 per cent. of its cost to be set aside every year, and the whole of the earnings of a single cable carrying messages at 1s. per word—as suggested by some very sanguine persons—will hardly suffice to provide the reserve fund, to say nothing of dividends for the shareholders. The bitter experience which the investors in the Direct United States Cable Company have purchased so dearly will make investors more cautious in the future, of entering into an undertaking which is recommended to them as competitive rather than necessary or remunerative. The shareholders in this company having paid £20 for their shares have eagerly availed themselves of the opportunity of selling them at about 50 per cent. discount, leaving the purchasers to compete or combine as they think conducive to their own interest. A great deal of silly talk has been indulged in at the enormity of the conduct of those who bought up the shares of the Direct Company for the purpose of carrying into effect a working arrangement between that company and the Anglo-American; but if it was deserving of censure to buy these shares, those who sold cannot be wholly blameless in the transaction.

If there were no sellers there would have been no buyers. The fact that the holders were willing to sell their shares was evidence that they had grown weary of a competition which, after three years of repeated disappointment and constant anxiety, had left them without reasonable prospect of a dividend. The experience thus obtained will not be lost upon those who may, at some future day, be asked to join in the Anglo-American telegraphic competition; but, if they should be disposed "to listen to the voice of the charmer," it may be well to remember that the cable laid in 1865, portions of which have been raised, is in an unsatisfactory condition, and except for the value of its core, will probably not again be disturbed in its ocean bed.

With respect to certain threatened proceedings by the Atlantic and Pacific Telegraph Company against the Direct Cable Company for the heinous offence of combination with a similar interest, it is curious to observe that by latest advices the intended plaintiff company has adopted a precisely similar policy to that against which it was to be used in opposition. Arrangements have just been completed for a fusion of interests between the two remaining American companies, and the Western Union will be left virtually in undisturbed control of the telegraphic business of the United States, it having been resolved to "pool" the earnings in the proportion of ¾ to the larger company, and ¼ to the Atlantic and Pacific Corporation. It will thus be seen that the movement in which the latter company was to be made the cat's-paw falls to the ground.—*The Railway News.*

60

The Success of Submarine Telegraphy.

It is only twenty years since the first attempt was made to lay a deep-sea telegraph cable across the Atlantic; and the oldest Atlantic cable now in use is only fourteen years old. There are now no less than six cables from Europe to North America; one from Europe to South America; two running the length of the Mediterranean, the Red Sea, and across the Indian Ocean to Bombay; one extending from Madras to Port Darwin, one from Sydney to Wellington, and many others of less length in different parts of the world. There are probably not far short of 100,000 miles of deep-sea cable laid and in daily working in all parts of the world; and an additional 20,000 miles are projected, and likely at no distant date to be actually put into operation. These figures alone are sufficient to dispose of any doubts as to the success of this branch of modern telegraphic engineering. When we consider the difficulties to be contended with in the construction and maintenance of a deep sea cable, this success is the more surprising. A thousand theoretical dangers may be suggested which would be likely to interfere with the effective working of a solitary line, lying miles deep, far from human ken, on the bed of the mighty ocean; and yet, as a matter of fact, interruptions are of rare occurrence, and cause, thanks to duplicate routes, little inconvenience to the general public. With all the difficulties and delays of re-transmission through alternate lengths of land wire and of submarine cable, a message may be sent to the Antipodes and its answer received in little over twelve hours. Mishaps must, and do, occur at times; but they are actually less frequent than the disasters to lines laid overland, for even "land lines" are not free from risk. To say nothing of the effects of hurricanes and thunderstorms in temperate climes, the elephants, monkeys, white ants, and other kinds of tropical fauna in uncivilized lands, would seem, if possible dangers were always realized in practice, to render the life of an overland telegraph line very precarious. But fortunately submarine dangers may even be guarded against. The "shore ends," which are liable to damage from friction against the shingle or rocks of the coast, or to be picked up, fractured, or otherwise injured by the anchors of passing vessels, are protected by heavy coats of thick wire. The Atlantic cables are exposed to the danger of, and have even now and then been broken by, the grounding of huge icebergs, which have crashed along the shallow shore, and broken even the thick iron-bound cylinders to which the shore ends may be compared. But such violent "wear and tear" is not usual, though other dangers naturally suggest themselves. Reposing on the deep bed of the ocean,

free from the disturbing influences of wind and wave, the thin black line is liable to the attacks of various enemies which may bore through the comparatively soft covering, and expose the delicate copper wire to earth contact. In the Arctic and Antarctic regions narwhals may pierce the gutta-percha while rooting about for their food, while in the tropics swordfish and sawfish are equally likely to inflict similar injury on the cable. The Penang-Singapore line has been once interrupted by the blow from the toothed beak of a sawfish, which ripped open the outer sheath and fractured the internal wire. The heat of the tropics alone would be thought to be sufficient to interfere with the effective working of deep-sea cables, the gutta-percha covering of which is rendered soft and easily penetrable by the great warmth of the water. The active enemies of the lines might then find their work of destruction easy, but, in fact, the insects of which we have heard so much of late generally content themselves by scooping shallow channels along the surface of the gutta-percha, which they do not find to their liking. Even such dangers can be obviated by coating the cables laid in warm water with a solid metal sheath, which will protect them from all injury. We have referred to these possible enemies of submarine cables to show that they exist more in imagination than in fact; the improvements effected in the manufacture of the cables render them proof against nearly every kind of enemy. Temporary delays do occasionally occur, but even these may be obviated by securing duplicate routes in every case.—*The Colonies.*

Cables. Jan 79

In a letter to the *Times* Mr. Richard Herring contends that the duplex system does not double the working capacity of the wires; that the longer the wire the more "steady" must be the sending; that on so long a cable as that of the Anglo-American very little more if as many as half the number of words extra as are now transmitted "single" will be possible when the cable is balanced for "duplex" sending. In reply to the letter of Mr. Herring referred to, Sir James Anderson writes to contradict the statement that, under the duplex system, no greatly increased power is obtained. He says: "Upon our Marseilles-Malta cables, a distance of 825 miles, we are to-day working simplex fifteen words per minute, duplex twenty-six words per minute. As far back as March, 1877, the working increase of speed upon our Bombay-Aden cable, which in electrical capacity about equals the Anglo-American cables, was 40 per cent. Upon the Aden-Suez cable, a distance of 1,460 miles, the increase was 60 per cent., and upon the Marseilles-Malta cable at the same date the increase was 71 per cent. To-day Marseilles-Malta averages 84 per cent. increase in regular working. Upon our Bombay-Aden cable the first day duplex was established, the increase was 40 per cent., on the second day, 67·27 per cent.; and on the third day, 72·72 per cent. I have not at hand any more precise data; but I am within the mark when I assert that we can command a steady increase of 70 per cent. in favor of duplex over simplex upon all our long sections, and that we can as a *tour de force* upon our short sections between Marseilles-Bona and Malta-Bona reach 100 per cent. increase."

61

CABLE SIGNALLING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read with great interest the letter of Richard Herring, Esq., on "Submarine Telegraphy," published in your paper of 21st ult. His treatment of the subject is purely scientific, and free from theory; and it is to be hoped that the obvious conclusions which he has drawn from the well-established facts in regard to the movements and effects of electric currents will lead to the utilisation of those facts, so that the *maximum* speed of transmission of signals through long submarine cables will be obtained; and thereby greatly increase their working capacity, and necessarily their profits, and perhaps justify the companies to reduce their tariffs.

Paragraph No. 16 of his letter gives the welcome information that he has a device to so utilize the well-established facts as to produce the great result, that is, the maximum speed of transmission.

It is sincerely to be wished that he is not deceived as to the practicability of his "device," and that he does not give to us hopes that may soon be disappointed, like many of those promises of the *great* and *modest American Inventor!!!* who announced in the newspapers that he had discovered the means to render noiseless the movement of trains of waggons on the elevated railroads in New York City, which noise, one of the New York newspapers with becoming gravity announced, was to be bottled up by the great discoverer, and to be sold to the Government to be used as fog whistles on the sea coasts. The facts stated by Mr. Herring are not theoretical deductions, but well established and uncontroverted facts, and there certainly cannot be any room for correction of his statements. The causes assigned for some of those facts, namely, for the differences of duration of charge, and of discharge, are purely *theoretical*, and may or may not be the true causes; nevertheless, the facts remain established.

It must be a matter of great astonishment that those facts, so well known, and upon which all the known systems of telegraphy are based, have not been applied in such a combination as to obtain the great result. The very fact that no such result has been obtained must suggest to everyone great doubts as to its practicability. The means capable of producing this result are so clearly demonstrated by those well known facts themselves that it really seems a wonder why no device to use these means has not long since been discovered; and the failure hitherto to make such a discovery almost forces upon the mind the conclusion that it is an impossibility. It may be, however, that science will show that this is not impossible, as it has so many other things which but a few years ago were deemed impossible.

While I will not presume to suggest even any correction of the statement of facts by Mr. Herring, I beg to submit a few remarks. In paragraph No. 14 Mr. Herring states:—

"When a conductor has received a charge of one kind of electricity, and is then put to earth at both ends, and also a charge of an opposite kind of electricity is sent into it from both ends, the conductor is restored to its neutral state in a duration of time not longer than that of the charge, whatever this latter duration may be."

This certainly is not a theory, but is a self-evident fact; but the great problem has been how to arrange to send at the proper time the opposite kind of electricity into the cable at the receiving end. That accomplished, the great result is obtained, and with impatience we await the promised disclosure of the device, and with sincere hopes that it may prove to be successful.

From reference in Mr. Herring's letter to "marks in special paper" I infer he employs on his receiving instrument paper saturated with some chemical solution. I believe that of all chemical solutions that of iodide of potassium is the most sensitive to the electric current, but its use has, I believe, been abandoned because of the evanescent quality of the marks. It would, no doubt, be a great *desideratum* if those marks could be made permanent as these signals sent through long cables, such as those crossing the Atlantic Ocean, could be recorded in Morse characters.

I may state, as an evidence of the great sensitiveness of iodide of potassium to the electric current, that I have been present when 200 words were perfectly recorded in Morse characters in one minute through a resistance of 37,730 ohms, with ten cells small size Leclanché battery. I have also seen 500 words recorded in one minute through 10,220 ohms with three cells of same size and kind. Perhaps some of your readers may know of some process by which the marks may be made less evanescent, or even permanent.

INQUIRER.

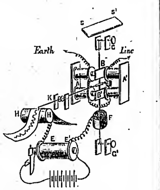
London, Dec. 30, 1878.

62

AILHAUD'S RECORDER FOR SUBMARINE CABLES.

THE currents employed on submarine lines being very weak, the electro-magnetic force of the receiver is not sufficient to overcome the inertia of the parts usually employed for recording, and more especially the friction of the paper slip against the inker.

We know how Sir William Thomson has obviated this difficulty in the construction of his Siphon Recorder. M. Ailhaud has just devised a small instrument which fulfils the same purpose.



Two electro-magnets A and A' are arranged as shown in the figure; two small magnetic armatures B, B', face the soft iron cores. These are carried by an aluminium wire, terminating below in an iron point, which dips into an iron mercury-cup F. To the centre of this wire, which is kept vertical by cocoon fibres wound upon adjusting screws G, G', is fixed a long slender indicator of aluminium, C. The received current thus deflects the indicator according to the direction in which it passes through the coils.

The recording is effected by the action of an induction spark upon a chemically prepared slip of paper which is carried by a metallic cylinder H, H, below the marking point.

The induction coil furnished with a contact maker, is actuated by a battery of large-surface plates, its ends E, E', being connected, one with the mercury cup, the other with the cylinder H, H. Thus, when the vibrating contact-maker is in action, a sparking is produced between the point and the paper slip; and inasmuch as there is no friction, the movements of the indicator are perfectly free. Two stops, K, which limit the extent of these movements, and a directing magnet S, S', complete the arrangement.

This receiver works very well with a local circuit comprising a Callaud element and ten thousand ohms resistance.

Upon the Marseilles-Algiers cable it is worked with five cells. The chemical paper is impregnated with a solution of potassium iodide and starch.—*Annales Télégraphiques.*

UNDERGROUND LINES IN PHILADELPHIA.—In 1877 several underground lines were laid in Philadelphia after a plan of Mr. David Brooks, and in connection with the working of the city railways. One of these lines crossed the Schuylkill river. The line consists in cotton-covered copper wires laid together into cables and pulled through iron pipes, which are then filled with paraffin oil. In this way fifty No. 18 copper wires are easily drawn into a pipe 1 inch in diameter. The most convenient length for drawing in and splicing is 1,000 feet. The oil solidifies at 20° below zero F. The insulation is 2,500 megohms per mile at 40° F. The system, which is specially useful for telephone circuits, has been patented in all foreign countries, and a company has been formed to work it under the title of the "Brooks Underground Telegraph Construction Company, Limited," Philadelphia.

WE have received the following small drama from our facetious correspondent *Will-o'-the-Wisp.*

THE INVENTOR AND THE OFFICIAL.

SCENE.—The general Post Office, St. Martins-le-Grand.

BRITISH TELEGRAPH OFFICIAL discovered at his desk.

Enter an OLD INVENTOR.

B. T. O. *(Warmly.)* "How do you do, Mr. Crazytop? Delighted to see you. I haven't seen you for an age."

O. I. *(Humbly.)* "Pretty well, thank you. I've been very busy lately. I've got something good here to show you; a fine idea; save no end of money. I patented it a year ago, and I've been at work on it ever since."

B. T. O. *(Warmly.)* "Oh, indeed; I'm very glad to hear it. You know we are always ready to welcome any new thing."

O. I. "Especially if it's American."

B. T. O. "Hum. Let us see this instrument."

O. I. "There she is." [*Explains its merits.*] "You see that it will be a great saving to the service."

B. T. O. *(Warmly.)* "Well, we'll have it tried, Mr. Crazytop."

O. I. *(Humbly.)* "If you please, I should like to experiment with it a little while myself on a real line, so as to improve and perfect it. Of course I have no telegraph line in my house, and I must come to you for one."

B. T. O. *(Warmly.)* "By all means, Mr. Crazytop, if you pay for it."

City Notes.

Old Broad Street, Jan. 29, 1879.

The directors of the Anglo-American Telegraph Company
(Limited) have resolved (after placing £37,500 to the
credit of the Renewal Fund) to recommend to the
proprietors of the next half-yearly general meeting of the
company, to be held on the 7th February next, the
declaration of the following dividends, all free of income
tax:—1. A balance dividend of 1½ per cent. upon the
ordinary Consolidated Stock for the half year ended Dec.
31, 1878. 2. A first and final dividend of 3 per cent. on
the Deferred Stock for the year ended Dec. 31, 1878.
After paying the foregoing dividends there will be a
balance of about £3,587 to be carried forward to the next

63

account. The above dividend, together with those already paid, amount to 4½ per cent. upon the ordinary Consolidated Stock of the company for the year 1878.

The directors of the Direct United States Cable Company have resolved upon the payment of an interim dividend of 5s. per share, being at the rate of 5 per cent. per annum, for the quarter ending 31st December 1878, such dividend to be payable on and after the 15th February.

The report of the directors of the Eastern Telegraph Company, to be presented to the Thirteenth Ordinary General Meeting, 30th January, 1879, shows the Company's revenue for the six months ended 30th September, 1878, amounted to £307,347 19s. 6d., from which is deducted £56,339 17s. 3d. for the ordinary expenses of the Company, and £20,154 3s. 3d. for special expenditure during the half year, as shown in the annexed accounts, which, with £2,726 5s. 6d. for income-tax, leaves the sum of £128,127 16s. 6d. net profit. From this amount, £35,269 13s. 2d. the interest on debentures and the dividend on the Six per Cent. Preference Shares to 30th September, together with two interim dividends on the ordinary shares for the quarters ending 30th June and 30th September, 1878, amounting together to £92,425, have been paid, leaving a balance of £3,433 3s. 4d. to be carried forward. The several sections of the Company's cables remain in good working order, with the exception of the Lisbon Cable, which is now under repair. The Company's cable repairing ships, stationed in the Mediterranean and the Red Sea, are in efficient condition, and in readiness for the Company's requirements. The Joint Purse Agreement between the Indo-European Telegraph Department of H.M. Indian Government, the Indo-European Telegraph Company, and this Company, continues to work satisfactorily. By the resolution of the Extraordinary General Meeting of Shareholders, held on 9th August last, the directors were empowered to acquire the shares and undertaking of the Black Sea Telegraph Company (Limited), and to raise capital for the purpose; and for the laying of a new cable between Alexandria and the Island of Cyprus. The transfer of the shares of the Black Sea Telegraph Company has been completed, and the cable (from Constantinople to Odessa) is now worked as part of this Company's system. In accordance with arrangements made with H.M. Government the Company has connected Cyprus with Alexandria by cable, and is now constructing land lines in the island. The capital required for the new works has been raised by an issue of five per cent. debentures, payable 1st August, 1887, of which £181,900 has been issued to the shareholders up to this date. Two of the directors, the Marquis of Tweeddale (Lord W. M. Hay, M.P.) and the Right Hon. W. N. Massey, M.P., retire by rotation, and being eligible, offer themselves for re-election.

The report of the directors of the Western and Brazilian Telegraph Company, to be presented at the sixth ordinary general meeting, 31st January, 1879, states the total earnings of the year amounted to £92,882 1s.; the working expenses (including £1,737 3s. 3d. rebate on issue of A, B, and C debentures) charged to revenue were £72,552 4s. 2d., which, together with £17,066 7s. 8d. interest for the year on the A, B, and C debentures, gives a total of £89,618 11s. 10d., leaving a net balance of £3,263 9s. 2d. to the credit of revenue account. It goes on to say:—"The ordinary working expenses show a reduction as compared with last year. The expenditure on account of maintenance and renewals exhibits on the other hand a very considerable increase. The revenue shows a falling off, compared with the previous year, of £5,652 19s. 11d. The general stagnation in commercial affairs will in part account for this, and the numerous interruptions of the company's cables have also influenced the revenue. The revenue account is subject to the settlement of the question raised by the Brazilian Submarine Company as to whether, in consequence of the lengthened interruption of the Pará-Pernambuco section, this company should participate to the extent of one-third in their gross receipts, as provided by the agreement existing between the two companies. It has therefore been necessary to estimate the amount due under this agreement. The expenditure on maintenance and renewal account this year charged against revenue has been £38,194 6s. 10d. The repairs and the extensive renewals effected have involved an expenditure of £69,194 6s. 10d., of which £38,194 6s. 10d. has been directly charged to revenue, and £31,000 to renewal account. The directors regret that so small a net revenue has been earned; a very great permanent improvement has been effected in the lines by the substitution of sheathed cable for that originally laid down; and although more work in the same direction still remains to be done, your cables are more secure and are working better, with greatly improved chances of unbroken communication. The directors commenced proceedings against Mr. Heugh, the late chairman of the company, for sums of money which the Board are advised he is accountable for, and these proceedings are being continued under the bankruptcy."

The Globe Telegraph and Trust Company (Limited) announce the payment, on and after February 7, of interim dividends for the quarter ending 18th January of 3s. per share on the Preference Shares, being at the rate of 6 per cent. per annum, and 2s. per share on the Ordinary Shares, being at the rate of 4 per cent. per annum.

The Eastern Extension Telegraph Company have given notice that the half-yearly coupons on their Six per Cent. Debentures, due on the 1st proximo, will be payable on and after that date, at the Consolidated Bank.

On Jan. 24th the Indo-European Telegraph Company notified that "The Black Sea direct cable from Odessa to Constantinople being restored, communication is now re-established by the special Indo-European route to Turkey."

The managing director of the Brazilian Submarine Telegraph Company (Limited) states that their cable to Madeira is working perfectly, and that there is no interruption either on the lines or cables of the Eastern Telegraph Company between London and their terminus at Lisbon.

The following are the latest quotations of telegraphs:—Anglo-American, Limited, 58½-59; Ditto, Preferred, 84-85; Ditto, Deferred, 33-34; Black Sea, Limited, —; Brazilian Submarine, Limited, 6½-6¾; Cuba, Limited, 8½-9½; Cuba, Limited, 10 per cent. NEW YORK, FEBRUARY 16, 1879.

THE PAST AND FUTURE OF THE ELECTRIC TELEGRAPH.

The rapid development of the electro-magnetic telegraph as a vitally essential and important social political and commercial agency, is a marked feature of modern life and history. The task of bringing it practically into use was a difficult one. It was at first doubtingly received, and the claims of those engaged in its introduction were regarded with incredulity. Its wonderful advantages were soon, however, demonstrated, and the public convinced of its value and importance. Crude and defective as were the methods at first employed, the telegraph soon became indispensable, and active efforts were inaugurated for its establishment not only throughout this country, but the world. It is not necessary to recapitulate the steps by which it advanced from what was popularly regarded as a doubtful experiment to an assured success. Many of those who were engaged in the service during the earlier years yet live, and some of them occupy prominent telegraphic positions which their experience specially qualifies them to fill advantageously. Most of those who engaged in the work during those years were young men, active, enterprising and enthusiastic, and the result has fully justified their faith and enthusiasm. The telegraph now reaches every portion of the civilized world, and has even penetrated to sections not yet regarded as civilized, and in a certain sense through its means all nations have become one people.

This country has been foremost in adopting and extending the telegraph service, and in adapting it generally to the necessities and requirements of the public. In addition to the regular commercial telegraphs, the special apparatus and systems of the Fire Alarm, the Gold and Stock, American District, private lines, etc., were invented, originated and practically introduced here. The notable improvements in telegraphic systems and apparatus of late years have either originated or were first reduced to practical usefulness in this country. In fact, in telegraphic history the United States occupy the leading position, and in no other country is electricity so completely and generally adapted to public service.

That here the telegraph has been left to private enterprise, and has not been hampered and restricted by official management and control, has undoubtedly been an important element in its rapid development and improvement. The active competition, or the possibility of competition, has compelled telegraphic managers to avail themselves of all possible improvements which would enable them to do the business entrusted to them reliably, speedily and economically. Inventors have been encouraged and invention fostered, and the beneficial results of such policy have been strikingly manifested.

There can be no doubt but that the future of the telegraph will be even more brilliant and successful than its past. The use of telegraphic facilities is constantly increasing, and as the necessity for further improvements becomes apparent, they will as heretofore be forthcoming. It seems to be impossible to limit the possibilities in this respect, and it would be absurd to suppose that science and invention have been exhausted. The demand for telegraphic facilities constantly increases, and the use of the telegraph seems likely in the future to become as universal as it has already become indispensable.

The Proposed New Atlantic Cable.

The attempt to revive and carry out the Pouyer-Quertier scheme for the laying of two additional Atlantic Telegraph cables does not appear to be meeting with much encouragement. It is reported that the idea has, in fact, been abandoned, and that the new company will instead lease a cable from the Anglo-American Company—presumably the French cable from Brest to the Island of St. Pierre and Duxbury, Mass. What truth there may be in this report we cannot say, but it certainly would be a much more sensible arrangement than to incur the expense of laying two additional cables, neither of which are likely to be needed for some years to come.

It is well known that the cables now laid and in operation are more than sufficient for the transmission of all the business that is or is likely to be offered. Although the Direct United States cable has been interrupted for some time, there has been no delay of business, the Anglo-American cables being amply sufficient to supply the telegraphic facilities required between this country and Europe. The repair of the Direct cable has been delayed by unfavorable weather, but the break is located within a short distance of Tor Bay, N. S., and a few days of suitable weather will suffice for its repair. This is likely to occur at any time, and it is not probable that it will be much longer delayed. It must be remembered also that the success which has attended the efforts of Mr. Stearns and Dr. Muirhead to duplex the long Atlantic cable have materially developed their capacity, and this of itself obviates any demand for additional cables.

A large proportion of the capital invested in the telegraph cable business has been contributed in England, and the unfortunate experience of the promoters of and investors in the Direct cable enterprise, which eventually sunk from 50 to 45 per cent. of its capital, has put a stop to further investments in Atlantic cables by English capitalists. In order, therefore, to carry out the new scheme the necessary capital would have to be obtained in France, if obtained at all, and since the pecuniary failure of the first French cable, French capitalists have not manifested any eagerness for further similar investments.

When the Direct cable was laid there was quite an extensive system of opposition lines with which it could connect in this country. There is at the present time no such system available, and this would preclude the success of any new enterprise, even if other conditions were favorable. The enormous losses which have resulted from the attempts to establish competing systems in this country have naturally disinclined the public to make further investments therein, and the promoters of such schemes do not meet with favorable responses to their attempts to dispose of stock for the construction of new lines, which are not required by the business or the people of the country. The existing lines furnish all the facilities required, and at as cheap rates as will suffice to make the business remunerative to those engaged in it. For these reasons we have had and have no faith in new Atlantic cable schemes which require the investment of ten millions of dollars, most, if not all, of which would be unquestionably lost to the investors. The chief promoters of such schemes are cable manufacturers, who, in their desire to supply the cables which would be required, overlook or disregard the interests of those expected to supply the funds to carry them out.

THE SOCIETY OF TELEGRAPH ENGINEERS.

ON "THE WORKING OF LONG SUBMARINE CABLES."

BY WILLOUGHBY SMITH.

(ABSTRACT CONTINUED FROM PAGE 149.)

The object in the system introduced by Mr. Willoughby Smith was to keep up a constant test for insulation and continuity, and at the same time to communicate freely through the cable between the ship and the shore.

After pointing out how a condenser may be formed by placing a certain length of cable-core in an insulated tank, and how an imperfectly insulating condenser was actually constructed by placing a series of sheets of tinfoil and gelatine alternately one on the other, the author stated that he connected one set of alternate sheets of tinfoil to the shore end of the cable conductor, whilst the other alternate sheets were connected to the terminal of a very sensitive astatic mirror galvanometer, of which the other terminal was led to earth. Consequently, the current which passed through the sheets of gelatine flowed through the galvanometer to earth, and a constant deflection was registered so long as the cable was kept charged at a uniform tension. But if the tension were altered, or the direction of the current reversed, the change of the deflection was immediately noticed by the person in charge of the galvanometer on shore, with whom the person in charge of the batteries on shipboard could thus communicate, by a pre-arranged code of signals, without interfering with the insulation test, since the current passing through the gelatine plates was hardly sufficient to increase the deflection on the ship galvanometer.

To enable the person in charge of the shore galvanometer to communicate the continuity or speaking signal to the ship, two resistance coils of unequal resistance, and a key through which the cable could be connected to earth through either coil, were employed, so that a minute portion of the cable charge could be allowed to pass to earth, the contact through one coil giving a signal corresponding to the Morse dot, and that through the other coil a signal corresponding to a dash.

This system was reported upon very favourably by Mr. Latimer Clark and Sir W. Thomson, who testified that it solved the problem of giving an absolutely continuous test of insulation whilst allowing signals to be transmitted in either direction and tests to be applied for continuity. At the suggestion of Mr. Laws the resistance coils were afterwards replaced by condensers of unequal capacity, an improvement by which several advantages were obtained. This plan, however, was superseded by one which was suggested by Messrs. Thomson and Varley, in which a single condenser only was used, the signals being produced by reversals from a local battery, which increased or diminished the deflection on the ship galvanometer by induction through the condenser. Mr. Willoughby Smith's system of simultaneous testing and signalling, thus modified, was employed during the laying of the 1866 and the completion of the 1865 cables, allowing of the transmission of 164 messages between the ship and the shore. It was, said the author, soon apparent that a higher speed would be obtained by the use of a condenser than by the "curb key;" consequently, the system of signalling was continued after the laying of the cable, and a speed of thirteen words per minute was attained with perfect ease.

Subsequently, on his return home, Mr. Willoughby Smith further altered and simplified the arrangements as follows:—The cable at each end was connected with a switch playing between a "receive" and a "send" contact. To the former was connected a condenser of a capacity equal to 75 miles of the cable; the other side of this condenser being to earth through the receiving galvanometer. The "send" contact stud was connected with a reversal key, by which currents from a 10-cell battery could be transmitted through the cable. The operator at either station, when wishing to speak, would "switch over" to the stud marked "send," and commence sending reversals to represent the usual call signal; then "switch over" again, and wait until he received the reply to his call, when he reverted to the former contact, and transmitted what he had to communicate. With this simple arrangement the author had seen 25 words per minute received at Valentia from Heart's Content, through 1,900 nautical miles of cable, with the most perfect ease. If, said he, we consider what 25 words per minute really mean, we shall be better able to realise the credit due to those gentlemen who are what is termed "good mirror clerks." To obtain this speed, the sender has to manipulate the springs of the key so as to make 375 contacts per minute, and the receiver has to distinguish, in the same space of time, the true from the false in the 750 movements of the small beam of light which moves either to the right or left on a strip of cardboard placed before him. This system has now been in use for twelve years on the Atlantic cables, and has been adopted for working all the cables laid during that period; and for speed, simplicity, economy, and accuracy it has not been surpassed.

After giving a practical instance of the superiority of this system, the author stated that the only objection he had ever heard brought against it was that the mirror galvanometer is not a recording instrument. To meet this objection, the very ingenious but complicated and expensive "Syphon Recorder" of Sir W. Thomson, patented in 1867, was introduced. When this is used it replaces the mirror galvanometer as the receiving instrument, the other parts of the system remaining intact. Mr. Willoughby Smith gave a simple description of this recording instrument, and stated that, in his opinion, the mirror is the superior instrument.

In 1873, Sir W. Thomson and Prof. Jenkin conjointly patented "the Automatic Curb Sender"—a combination of the "curb key" and Sir C. Wheatstone's well-known "automatic sender." This instrument, in the opinion of the author, is a step in the right direction, but will be of little value until a suitable receiving instrument is discovered to work with it.

After pointing out that the use, in conjunction with a condenser, of resistance coils connecting the cable to earth could only be of detriment in the present system of working long cables, the author of the paper referred to the fundamental law of induction on which this system is based, and afterwards entered into some very interesting details as to the extreme minuteness of the current producing the signal on the mirror galvanometer when a condenser is used. Assuming the currents from ten Menotti cells to be sent into the cable on each contact at the sending station, then the amount of induced current passing through the receiving galvanometer would be equal to about 1-40,000th part of that current. The cable is only partially discharged between each signal, by each spring of the sending key being put to earth after it has been depressed to charge the cable. To give some idea of the very small amount of current which actually gives the signal, it was mentioned that a sempstress, whilst manipulating with her needle and thimble, generates a stronger current, and that a knife and fork inserted into a steak or chop at lunch produces a current of six times the amount.

In regard to the employment of electro-magnets with a view to increase speed of signalling, an experiment was described in which the induced magneto-electric charge totally neutralised the charge from the battery, so that no discharge could be obtained from the cable. Nevertheless, experiments with electro-magnets, placed in every conceivable way, gave results which were in all cases unfavourable to the employment of electro-magnets as shunts.

Referring to the application to long submarine lines of the duplex system of working, Mr. Willoughby Smith explained that the principle of signalling remains the same as that above described, but the receiving instrument at each station is so placed that the current sent to the distant station does not affect it. To insure good duplex working, a true balance must be established at the sending end, so that no current will pass through the receiving instrument when placed as a bridge between the real and the artificial cables.

In concluding the Paper, which was illustrated by a number of diagrams and some interesting fac-similes of signals received under various conditions by the syphon-recorder, Mr. Willoughby Smith said that, although wonderful progress had been made in electrical science during the last few years, he believed that we are only on the threshold of what we may be permitted to know, and that there are before us gleams of light which, if rightly pursued, will richly reward the patient and honest explorer.

66

the Board as to the "life" of a cable, was of no more value than that of other persons connected with telegraphic business, but they had only to look to facts as connected with their own business; and although he admitted that their experience might be exceptional, he did not think they would be justified in treating their cable as likely to have an undisturbed "life" of more than ten years. Experience showed that the West Indian seas were not favourable to the "life" of a cable. As to the remarks about the defective nature of the last cable laid for them—the india-rubber cable—it had been constantly under the consideration of the Board whether there was any fault attributable to the manufacturer; but it was impossible for them to ascertain whether the fault lay with, and could be brought home to, the manufacturer or not till the fault was reached. The cable, however, was constantly inspected and severely tested during its manufacture by Mr. Keith, who was now repairing it. The motion was then unanimously adopted, and the dividends having been declared, a vote of thanks to the Chairman and directors terminated the proceedings.

According to the report of the Telegraph Construction and Maintenance Company (Limited) the accounts for the year show a net profit of £87,746, after charging the interest on the Debentures. To this sum must be added £61,247 brought forward from last year, making a total of £148,993. From this amount is deducted the interim dividend of 5 per cent., paid 10th July, 1878, amounting to £22,410, leaving £126,583 to be dealt with. Of this sum the directors propose to distribute a dividend of 15 per cent., or £67,230, being at the rate of £1 16s., per share, and making with the amount already paid, a total dividend for the year of £2 8s. per share in cash, free of income tax, leaving £59,353 to be carried forward to the next account.

The Western and Brazilian Telegraph Company (Limited) notified on the 15th inst. that telegraphic communication has been completed from Para to Monte Video. This places the Company's entire system, including the new line into Maranham, for the *first time* in complete working order. The cables are now working from Para to Monte Video, including all the intermediate ports required by the Company's concession. During the last twelve months, out of the original Western and Brazilian line from Rio de Janeiro to Para, viz., 2,517 miles, 830 miles of new cable, nearly all sheathed, has been relaid in shallow waters, leaving but a moderate length in these waters which it will be necessary hereafter to renew. The engineers report that the original cable, laid in deep water, is in excellent condition.

The Anglo-American Telegraph Company's Brest cable was broken on the morning of the 23rd last, during a violent tempest, which had been raging for 36 hours. The cable was broken about 161 miles from St. Pierre, in 500 fathoms of water. The Company's ship has been ordered to sea at once to effect the repair.

The Direct U.S. cable is not yet repaired, there are therefore at present but two Atlantic cables at work both are, however, duplexed.

JOURNAL OF THE TELEGRAPH.

VOL. XII. NEW YORK, MARCH 16, 1879. WHOLE NO. 273.

A NOTABLE CELEBRATION OF THE INITIATION OF OCEAN TELEGRAPHY.

The Twenty-Fifth Anniversary of the Organization of the Company which led to the Establishment of Submarine Telegraphy Worthily Commemorated. Four of the Five Original Promoters Personally Participate in the Festivities.—A Remarkable Gathering of Distinguished Personages.

AT ten o'clock in the evening of March 10th, 1854, in the parlor of Mr. Cyrus W. Field, was signed the contract by which the New York, Newfoundland and London Telegraph Company was organized. The parties to this contract were Cyrus W. Field, Peter Cooper, Marshall O. Roberts, Moses Taylor and Chandler White. Peter Cooper became President of the company. The original purpose of the company was to complete a line 400 miles in length, from Cape Ray to St. Johns, Newfoundland, which had already been commenced, and thus by means of steamers to be run from the west coast of Ireland, to shorten the time required for communication to Europe from about two weeks, which were then required, to eight to ten days. The project had been taken up by Mr. Field, and through his earnest representations the gentlemen above named had been interested in it, and undertook to carry it through. The idea was naturally suggested that the line should be carried across the ocean, and Mr. Field accordingly obtained in March, 1854, from the Legislature of Newfoundland, a charter granting for fifty years an exclusive right to establish a telegraph from the Continent of America to Newfoundland and thence to Europe.

The land line was constructed across Newfoundland, much of the way through an unbroken wilderness. The difficulties of construction and the cost were enormous. In 1855, Mr. Field went to Europe and organized the Atlantic Telegraph Company to carry the line across the ocean. Most of our readers are familiar with the subsequent history of the enterprise. Through his exertions mainly the necessary capital was secured, and aid in ships was obtained from the American and British Governments. The cable was manufactured and two attempts to lay it in 1857 and 1858 failed, but the third was successful, and in 1858 the first telegraphic communication took place between England and America. The work had been pursued under most discouraging circumstances. There was but little faith in the practicability of transmitting signals through such long submarine lines, and less in the possibility of maintaining the line for any length of time even after it had been successfully laid. The fact that telegraphic communication had actually taken place between the two countries was, therefore, greeted with the wildest enthusiasm; congratulations, fêtes and celebrations of the event followed, and Mr. Field was the lion of the day.

There were, however, many who still doubted the actual transmission of communications over the line, but the evidences were so conclusive by the publication of news in London and New York within two days after the events recorded had occurred, that these were compelled to acknowledge that ocean telegraphy was an accomplished fact. The first public messages were congratulations between Queen Victoria and President Buchanan, which occupied in transmission 67 minutes each. From the first the cable worked very slowly, and with constantly increasing difficulty. Although the practicability of telegraphing over long submarine lines had been satisfactorily demonstrated, years were yet to pass before ocean telegraphy should be permanently established. The line soon ceased to work, and doubt and discouragement had again to be encountered and overcome. Mr. Field never lost faith in the enterprise, and made many trips to Europe in his endeavors to resuscitate the company and obtain the means for the construction and laying of another cable.

Of the four gentlemen who had with him engaged originally in the enterprise, Mr. White died two years after the organization of the N. Y. N. F. & L. Telegraph Company, and his place was taken by Mr. Wilson G. Hunt. These gentlemen adhered loyally and persistently to the enterprise which they had undertaken, and all lived to enjoy the success which ultimately crowned their exertions and sacrifices.

The civil war in this country had broken out in the meantime, and it was not until 1865 that another expedition was prepared. During the intervening years great improvements in submarine telegraphy and in the construction of cables had taken place. The building of the Great Eastern, which had proved a failure for the purpose for which it was originally undertaken, afforded a steamer of enormous dimensions, and which was better adapted to the purpose of laying ocean cables than any which had before been available. The cable was coiled upon the Great Eastern, and she sailed for Newfoundland. After 1,200 miles of cable had been payed out, by a sudden lurch of the vessel it was broken and the end lost. The attempts to recover it were unsuccessful and the expedition returned to England. The fates seemed indeed to be against success of an enterprise which had cost so much time, labor and money. Additional cable was, however, manufactured, and in 1866 the Great Eastern sailed again. This time the fates were more propitious, and the 2,000 miles of cable were successfully laid, and telegraphic communication between the old and new worlds permanently established. Communication was perfected July 27, 1866, and has never since been entirely interrupted. After landing this cable the Great Eastern returned to mid-ocean and after two months grappling found the end of the cable lost the previous year. It was brought up from a depth of two miles, connected with the cable remaining on board and carried safely to the Western shore.

After twelve years of incessant labor, in which he crossed the ocean nearly fifty times, Mr. Field saw the crowning effort of his life accomplished. Congress voted him a gold medal with the thanks of the Nation; while the Prime Minister of England declared that it was only the fact that he was a citizen of another country that prevented his receiving high honors from the British Government.

The success which had after so many years been obtained, and the demonstration of the practicability not only of laying, maintaining, and operating long submarine cables, but also of recovering them when broken or needing repairs, from great depths of water, was followed by a rapid development of ocean telegraphy in all parts of the world, until now every sea and ocean, except the Pacific, are crossed by these electric cords, which bind together all nations of the earth. When the Pacific cable shall be laid from our Western Coast to China and Asia, the telegraphic circuit of the world will be completed. It is the remaining ambition of Mr. Field's life to accomplish this, and having already been so successful in more doubtful enterprises, it is by no means impossible that this ambition shall be gratified.

A quarter of a century has passed away since the contract for the organization of the New York, Newfoundland and London Telegraph Company was signed. To celebrate that event, Mr. Field gave a reception on the 10th instant, at his residence in Gramercy Park in this city. It was indeed a notable event and notable assemblage. The invitation card was artistic, elaborate and symbolical of the occasion. It is surmounted by the coat of arms of Mr. Field's family—a shield, sable, bearing three sheaves of wheat or, between a chevron, argent. The crest is a hand and arm, gules, rising from clouds, argent, and supporting a globe, all of the heraldic tinctures being beautifully printed in colors. The escutcheon is supported on one side by the British naval flag, on the other by the Stars and Stripes; and at the base is embossed on a silver scroll the appropriate motto, "Sans Dieu, Rien," The four quarters of the world that the cable has knotted together have their places in the four corners. Europe sits, queen-like, upon a bull; bronzed Asia, with golden armlets, is borne on a kneeling elephant, two Brahmins beside her; Africa perches upon the hump of a camel, and America, with feather mien, bestrides a bison. Boughs, berries and leaves twine themselves round the medallions, and a cable, coiled and twisted, weaves itself into the letters "C. W. F." On one side is the date of the cable's birth, March 10, 1854; on the other the date of the celebration, March 10, 1879. In the centre is an oblong card of invitation. "Mr. Cyrus W. Field requests the pleasure of ——'s company Monday evening, March 10, from nine to twelve, Gramercy Park, New York, February 24, 1879." At the foot is the dining-room, with map and globe, and like-

THE DIRECT UNITED STATES CABLE COMPANY.

Abstract of the Report to be presented at the third ordinary general meeting of the Company, on Friday, March 21:—The Directors submit with this report the usual statements of account for the half year ending 31st December, 1878. The revenue for the half year, after deducting outpayments, amounted to £89,943 14s. 8d. For the corresponding half year of 1877, the amount of revenue, after similar deductions, was £84,217 12s. 10d. The working and other expenses, interest on debentures of the old Company and income-tax amount to £21,748 0s. 11d., leaving a balance of £68,195 4s. 9d. as the net profit for the half year, making, with £2,933 3s. 7d. brought forward from the previous half year, a total of £71,128 8s. 4d. In the corresponding half year of 1877 the expenses and payments above mentioned, and cost of repair incurred during that period, amounted to £25,048 2s. 10d. Interim dividends of 1½ per cent. each for the quarters ending 30th September and 31st December, 1878, together amounting to £30,355, have been declared and paid. A sum of £32,500 has been added to the reserve fund (thereby increasing it to £73,139 14s. 9d.), and a further sum of £3,000 has been written off the preliminary expenses, leaving a balance of £5,273 8s. 4d., which has been carried forward. The necessary six months' notice was given in July last of the intention to pay off the debentures of the old Company, and the amount and interest have since been paid. It was deemed expedient that a member of the Board should proceed to the United States and Canada with reference to questions which had arisen upon the reconstruction of the Company, to complete the necessary arrangements with associated companies, and generally to investigate the working of the Company's system on the western side. Accordingly, during the autumn of last year Captain Mayne visited the Dominion and the United States. The agreements between the Atlantic and Pacific Telegraph Company and the old Company, and between that Company and the Franklin Company, have been adopted with some modifications, and an agreement to carry out the negotiations with the Dominion Telegraph Company of Canada, referred to in the report presented to the members at the last half-yearly meeting, is now under consideration by that Company. The arbitration proceedings between the liquidators of the old Company and Mr. Loeffler, one of the dissentient members, have extended over a period of ten months, and occasioned considerable labour to your Directors and the staff. It is with much satisfaction the Directors state that the proceedings were closed on the 5th February last, and they now await the arbitrator's award. The Muirhead duplex system has been applied to the main cable. An interruption of the main cable occurred on the 4th January last. The break has been located at about six knots from the Torbay station. An interruption also occurred in the short cable on the 12th February. This break has been located on Brown's Bank, about 290 knots from Rye Beach. Both breaks are in shallow water, and, with favourable weather, the repairs will be speedily effected. Owing to the operation of the agreement with the Anglo Company, the receipts of this Company are not affected.

Underground Telegraph Wires.

In the Assembly, at Albany, on the 19th, Mr. Grady presented a bill relative to the locating of telegraph wires throughout the State, the first section of which provides: "Any telegraph company incorporated under the laws of the State of New York shall have the right to lay under ground, in any city or town of this state or along any highway thereof, its wires to make such telegraphic connections as may be called for in its articles of association, subject to the provisions under which poles for carrying telegraph wires are now placed in towns, cities, or along public highways or post roads. feb. 79

THE PROPOSED NEW FRENCH CABLE COMPANY.

With reference to the proposed new arrangement for Atlantic telegraphy, the Continental Exchange Agency sends the following extract from the Paris *Bulletin Financier*:

"We are informed that the formation of a new French company has been decided upon, having for its object the exploitation of a trans-atlantic cable altogether distinct from that of M. Pouyer-Quertier, and of which the bases will be published in a few days. The new company will take over the existing cables between Brest and St. Pierre and the United States of America, as well as the concession accorded by the French government in 1868, which assures important advantages on all ulterior concessions. The company will provide for the laying of new cables between Brest and North America for the period when the existing cables shall no longer be in a condition to work. The capital is fixed at twenty million francs, which is amply sufficient to cover the expenses of construction and of laying in the best possible conditions, as well as for meeting the first charges and constituting a fund for the working expenses, together with a first installment toward a reserve fund. The new company will be directed by a French council of administration. The communications, in case of interruption, are guaranteed by conventions with the English companies whose lines are in relation with Brest by submarine cables already existing. One of the most important financial establishments in Paris is now occupied with the issue of shares." apr. 79

Anglo-American Telegraph.

The half-yearly meeting was held at the Cannon street hotel February 7th, Viscount Monck, the Chairman, presiding.

The report states that the total receipts from July 1 to December 31, 1878, including a balance of £15,120 carried over to the last account, amount to £309,570. The total expenses of the half year, including income-tax and the ordinary repair of cables, amount to £55,983. The expenses of the special repairing expedition of 1878, amounting to £14,146, have been charged to the renewal fund, viz.: £9,007 in the half year ending June 30, 1878, and £5,138 in the half year ending Dec. 31, 1878. The directors have set apart to the renewal fund the usual amount of £75,000, leaving a balance of £178,587 disposable for dividend. One quarterly interim dividend, at the rate of 4 per cent. per annum, free of income-tax, was paid on Nov. 1st last, absorbing £70,000, leaving a balance of £108,587, out of which the directors recommend the proprietors to declare a final dividend of 1½ per cent., free of income-tax, amounting to £105,000, making a total distribution for the year ended Dec. 31, 1878, of 4½ per cent. upon the ordinary consolidated stock of the company; 6 per cent. upon the preferred ordinary stock, and 3 per cent. upon the deferred ordinary stock, leaving a balance of £3,587 to be carried forward to the next account. The traffic receipts for the last six months of 1878, as compared with the corresponding period in 1877, show an increase of £16,241. The expedition composed of the s.s. *Seine* and s.s. *Calabria*, fitted out last spring, failed to repair the 1866 cable, and returned to this country on the 27th July last. The failure was caused by oxidation of the iron wire and decay of the hemp of which the outer covering of the cable consisted. The company's repairing ship, the *Minia*, has successfully diverted the Duxbury cable; the directors trust that this cable, as now laid, will be free from interference by fishing vessels, whose anchors have been the cause of nearly all former interruptions. The three deep-sea cables and the rest of the company's system are in good working order and condition. Since the last half-yearly general meeting of the company, Mr. J. B. Stearns has been engaged upon both sides of the Atlantic in placing his duplex system of telegraphy upon one of the company's cables between Valentia, Ireland, and Heart's Content, Newfoundland. The possibility of duplexing the company's deep-sea cables has now been placed beyond a doubt; but as the royalty to be paid for the use of the patents is fixed by agreement according to the increase of speed to be obtained, the system will not be accepted and paid for until the percentage of increase shall have been ascertained and settled by regular working of the traffic for a reasonable time. The directors have sanctioned an arrangement by which the employés may secure the payment to themselves of a limited sum at a given age, or to their families in case of death—the company paying one-half of the premiums required for this purpose. A resolution approving this arrangement was submitted to the meeting.

The chairman explained the report very fully, and strongly urged as a matter of justice and policy the approval of the arrangement to provide for the future of the employés of the company. This met with considerable opposition. In the course of the discussion which ensued the chairman said that for this fund £2,000 would be required, of which it was proposed that the company should pay one-half and the employés one-half. The employés contribute in proportion to their salaries, and the sum they will ultimately receive will be in proportion to their contributions. No man can receive more than £1,000 (about $5,000) but there may be smaller payments.

In reference to the proposed new company in opposition to the existing Atlantic Cable companies (the Pouyer-Quertier concession), the chairman said:

"I have no doubt many of you have seen in the money article of the leading journal yesterday morning a statement from Paris, which I take leave to say was written with a view of what is called 'forcing the hands of your directors' at the meeting today. It stated that the company was formed, and the caution money paid, and everything ready. I have nothing to do with that; but the fact is the caution money has not been paid. That is a matter of fact, and all I have to say on the subject is this, that your directors are fully alive to the importance of any attempt of this kind; and they have taken, and are taking, every means in their power to protect your interests, and I trust you will have sufficient confidence in them to leave the matter in their hands, and not play the game of the enemy by forcing us into premature disclosures. I don't think there is any other matter I need make any observation upon. I congratulate you on the state of your property. The cables are working well. The French cable, which has now been in the water nearly ten years, is in better condition for working than when it first began its career, and we trust will live many years more. The other cables are in excellent condition; the traffic is prosperous, and I trust that we shall be relieved from any fears, from any quarter, of interference with the prosperity of our company. I beg now to move the adoption of the report and accounts, and the payment of the dividend recommended in the report."

It was further stated by the chairman that 90 per cent. additional work had been got out of the cable upon which experiments had been made from the use of the duplex system.

The resolution approving and adopting the report and accounts was carried unanimously.

The retiring directors, Sir Daniel Gooch, Bart., M.P., and the Hon. Robert Grimston, were re-elected, as were the retiring auditors, Messrs. Dean and Glasse.

The Chairman then proposed a resolution authorizing the Board to constitute a superannuation fund, which was seconded by Mr. Itate, but met with considerable opposition from the meeting.

An amendment was proposed to the effect that the consideration of it should be postponed until the next general meeting, which was agreed to by the majority.

The Chairman said he had proxies in its favor representing £3,000,000 of stock, but if the amendment were withdrawn he would hold the matter over until the next meeting.

This was unanimously agreed to, and the meeting separated.

The French Atlantic Cable Broken.

The French Atlantic cable, operated by the Anglo-American Telegraph Company, is broken 161 miles from St. Pierre Miquelon, in 500 fathoms of water. The repairing steamer has been ordered to proceed to raise and repair it, and unless the weather should prevent, it will be speedily restored.

Application for Telegraph Cable Privileges Refused.

In the United States Senate, on Monday, Feb. 24, Mr. Hamlin, from the Committee on Foreign Relations, reported adversely on the Senate bill to grant to the American Ocean Cable and Telegraph Land Wire Association of Philadelphia, the right of way and privilege to lay, land and operate submarine

The Direct United States Cable Company.

At the third ordinary general meeting of the Direct United States Cable Company, held at the Cannon-Street Hotel, London, March 21st, the Chairman, Mr. John Pender, M. P., in moving the adoption of the report, (a synopsis of which was published in the last number of this paper,) said that the company had now, after a great deal of obstruction, arrived at a satisfactory position, although a great deal of money had been expended to secure that position. One of the dissentient holders had made a claim of

£76,143, or £76 per share, when the par value was only £20, but the amount awarded to that person was only £13,000, which sum was offered to him by the liquidators before he went to arbitration. That business had cost the company about £10,000, which might as well have been thrown into the sea. There had been a great deal of talk about a new French cable, and he had gone to Paris to make inquiries relative thereto. He was astonished to find that the promoters of the scheme were so little acquainted with facts and figures; for they were bringing before the public a scheme with a capital of £2,400,000 for two cables, which was close upon double the capital of the Direct Company, without anything like their security, and the shares of the Direct Company were at a discount of close upon 50 per cent. He pointed out to the men connected with the new scheme that the moment the cable was laid, competition would arise, and a 6d. tariff might be adopted; and, although there would be a diminution in the receipts of the Direct, it would entirely prevent the new company paying a shilling to their shareholders. There was no need whatever for the new cable, seeing that they (the Direct Company) had applied the duplex system, and thus increased their carrying powers. The result of the visit was that the promoters had wisely hesitated; for to float a company with the knowledge of the facts he had communicated to them would incur a grave responsibility, which might some day be used against them. He was told that the *amour propre* of the French people must be satisfied; that the whole of the great telegraph enterprise centered in England; and that France should share that; although, as he said, France only contributed 11 per cent. of the Atlantic traffic. He accepted that sentiment, believing that telegraphy should be of an international character, and to meet it the Atlantic Company proposed to establish a company in France, with a French representation, using the Brest cable for the scheme, and to work in harmony with the existing systems. But, had it not been for the change which had taken place in the reconstruction of the Direct Company, he believed that the new scheme would have been proceeded with. The promoters of the French scheme stated that they had received a concession from the French Government, and that the head of the combination was to receive £20,000 for the concession, with a permanent position as president of the company; that the manager of the company was to have a remunerative position, and that the financiers backing it were to receive a large sum of money. As to the concession for which the £20,000 were to be paid, he said that the Anglo-Company already held a concession from the French Government, which gave them great advantages, with a preference over all the French traffic—that concession having eleven years still to run. He was unable to see a copy of the concession to the new scheme, but was told that it merely included a landing-right, which the French Government were prepared to give to any respectable company which might ask for it. He had no doubt that the promoters of such a scheme would be enriched, but it would have to come out of the pockets of the French subscribers, and he was yet hopeful that the scheme would fail, as had previous ones. Mr. Pender then spoke of the relations of the Direct Company with the governments and companies on the other side of the Atlantic, which he considered were satisfactory; and stated that during the present session the company's position would be distinctly recognized by the Canadian Parliament. The Americans were rather more disposed than usual to encourage telegraphy, but they did not, like the English, invest to any extent in that enterprise. He referred to the advantages accruing to

the public, especially through the medium of the cheap tariffs to the press, arising from telegraphy, which, however, he contended, would be destroyed were competition established by new companies being formed.

THE DIRECT UNITED STATES CABLE REPAIRED.

The break on the Direct Cable, about two miles from Tor Bay, N. S., was repaired March 20th, and business over it was immediately resumed. This interruption occurred January 3d, and as it was in shallow water, could have been repaired in a few days, had it not been for unfavorable weather incident to the season.

It was found upon examination of the fractured ends of the cable that it had been originally laid on a ridge of rocks, and the sheathing wires had been gradually ground down to needle points, and the cable finally broken.

The Direct United States Cable Company.—Report for Last Six Months, 1878.

The third ordinary general meeting of the Direct United States Cable Company was held at the City Terminus Hotel, London, March 21st. The report of the directors for the half year ended December 31st, 1878, was presented and adopted. The report states that the revenue for the half-year, after deducting out payments, amounted to £89,943, 14*s.* 8*d.* For the corresponding half-year of 1877, the amount of revenue, after similar deductions, was £84,217, 12*s.* 10*d.* The working and other expenses, interest and income tax, amounted to £21,748, 0*s.* 11*d.*,

leaving a balance of £68,195, 4*s.* 9*d.*, as the net profit for the half year, making, with £3,003, 3*s.* 7*d.* brought forward from the previous half-year, a total of £71,128, 8*s.* 4*d.* In the corresponding half-year of 1877, the expenses and payments and cost of repair amounted to £25,010, 2*s.* 10*d.*

Interim dividends of 1¼ per cent. each for the quarter ending 30th September and 31st December, 1878, amounting to £30,355, have been declared and paid. The sum of £32,500 has been added to the Reserve Fund, increasing it to £73,139, 14*s.* 0*d.*, and a balance of £5,273, 8*s.* 4*d.*, has been carried forward. The debentures of the old company have been paid off.

It was deemed expedient that a member of the board should proceed to the United States and Canada with reference to questions which had arisen upon the reconstruction of the company, to complete the necessary arrangements with associated companies, and generally to investigate the working of the company's system on the western side. Accordingly during the Autumn of last year Captain Mayne visited the Dominion and the United States. The agreements between the Atlantic and Pacific Telegraph Company and the old company, and between that company and the Franklin Company, have been adopted with some modifications, and an agreement to carry out the negotiations with the Dominion Telegraph Company of Canada referred to in the report presented to the members at the last half-yearly meeting is now under consideration by that company. An interruption of the main cable occurred on Jan. 4 last. The break has been located at about six knots from the Torbay station. An interruption also occurred in the short cable on Feb. 12. This break has been located on Brown's Bank, about 100 miles from Rye Beach. Both breaks are in shallow water, and with favorable weather the repairs will be speedily effected. Owing to the operation of the agreement with the Anglo Company the receipts of this company are not affected.

Another Atlantic Cable Company Projected.

A Paris paper, *The Bulletin Financier*, says: "A cable company is now organizing, with 20,000,000 francs ($1,000,000) capital, under the auspices of an important Parisian financial establishment. It will acquire the existing Brest and St. Pierre Cable, with the concession of 1868, assuring important advantages over all later concessions." This company is intended to work in conjunction with the existing system, with the view of antagonizing the Pouyer-Quertier scheme.

The International Telegraph Conference.

The date of the meeting of the Congress has been fixed for the 10th of June. This is the first meeting of the conference in London.

The Telegraph in China.

We hear that, through the enterprise and wise policy of the Viceroy, His Excellency Li Hung Chang, telegraph stores have been purchased, and that under the direction of Mr. J. A. Betts (the director of the Imperial Torpedo College, Tientsin) the *first* telegraph line for the transmission of *public messages* [illegible] be erected, and will probably be in working order within three or four months from this date. [illegible] will be a line of some 40 miles in length, and [illegible] no doubt, be very rapidly extended. Thus we [illegible] expect to find that within the next decade the [illegible] of electricity in China will be as much a fact as [illegible] Europe or America.—*The Telegraphic Journal.*

72

A CABLE manufactured by Mr. Henley has been sent out to Russia, in order to be laid across the Caspian Sea.

THE acquisition by the Government of the undertaking of the United Kingdom Telegraph Company having been recently brought before Parliament, and a memorial presented to it by Mr. J. M. Gadd, alleging frauds against the directors of that company, these gentlemen have published a declaration refuting the assertions of the memorial in question.

MR. WILLOUGHBY SMITH's recent paper to the Society of Telegraph Engineers on the "working of Submarine Cables," has been separately published as a monograph, and will form an interesting contribution to the history of the subject.

MR. CHARLES STEWART, M.A., has been awarded a silver medal by the Academie Nationale of Paris, for his treatises on "International Correspondence, by means of numbers, an easy method whereby people of different nations may readily communicate with each other," and "how to learn the Morse Alphabet in half an hour." These books are published by Messrs. E. Marlborough and Co.

[From the *Journal Télégraphique*.—Translated for the JOURNAL OF THE TELEGRAPH.] Apr. 19

EXPERIMENTS WITH A NEW DESCRIPTION OF TELEGRAPHIC CABLE.

By M. ROTHEN, *Sub-Director of Swiss Telegraphs.*

A COMPANY has recently been organized at Cortaillod, in French Switzerland, under the name of Berthoud, Borel & Company, for the purpose of manufacturing and introducing a new description of telegraph cable, the composition of which differs materially in the conductor and in the insulating material employed, as well as in the manner in which it is manufactured, from any at present in use. Exteriorly these cables somewhat resemble those made by Rattier & Co., at Paris, and well known in France and in other countries, where they have been extensively used. This exterior resemblance is, however, the only one, as, in fact, the conductor in the new cable is of lead instead of copper, and the dielectric a resinous or sulphurous substance instead of gutta-percha or india-rubber, and the protecting covering or sheath is a lead tubing. Notwithstanding the quasi solidity and small flexibility of the dielectric substances employed, the new cables are not less supple than those heretofore used, and in this respect are not inferior to other cables. The conductor, in this as in gutta-percha covered cables, is placed in the centre of the dielectric, and strictly retains this position in spite of the manipulations to which the cable may be subjected.

This is not the place to discuss the reasons which have governed the manufacturers in the selection of the materials used; but if to the method of manufacture is added the consideration that the cost of the new cable will be much less than that of those at present employed, it will be of interest and importance to learn the results of experiments with specimens of it, made in the presence of experts at Berne.

The specimens furnished by the company for experimental purposes were three in number, the first and second only differing in the diameter of the core, and the third in the substance of the dielectric; a sulphurous material replacing the resinous substance used on the former. These three specimens, which we will designate as cables No. I., No. II. and No. III., had but one conductor each, and were intended, as is shown by the character of the protecting sheath, for underground purposes, this wrapper not having sufficient tensile strength to stand immersion in considerable depth of water. The following were the length, diameter and weight of the three specimens of cable tested:

	No. I.	No. II.	No. III
Length of specimen...........	295 feet	361 feet	328 feet.
Diameter of core..............	·56 inch	·67 inch	·61 inch
Outside diameter of dielectric.	·114 "	·148 "	·184 "
Outside diameter of protecting wrapper........................	·189 "	·232 "	·236 "
Weight of specimen 328 feet....	30½ lbs.	45½ lbs.	46 lbs.

These cables had been immersed in water for five days before commencing the tests.

For the purpose of comparison, a copper wire, covered with gutta-percha, of the following dimensions, length 328 feet; diameter of core ·55 of an

[illegible] outside diameter of gutta percha ·169 inch, were similarly immersed. In making the tests the following apparatus were used:

1. A Thomson's Galvanometer.

2. A Daniell's battery of 150 cells; a Wheatstone Bridge on the basis of Siemens Units; an artificial resistance of 328,800 Siemens Units, composed of glass tubes filled with a weak solution of sulphate of zinc, with large terminal plates of amalgamated zinc.

3. A special key.

The *Electro-static Capacity* was first determined, then the *insulation*, and lastly the *resistance of the conducting core*.

Electro-Static Capacity.

The charging was done with five Daniell's cells, and the process of charging was observed at the galvanometer. Three observations were taken for each sample, of which the following table, giving the deviations of the spot of light, shows the results.

Copper wire covered with gutta-percha.	No. I.	No. II.	No. III.
148	102	109	148
150	105	110	143
148	105	113	148
Average 148	104.3	112.7	146.3

While, for absolute accuracy, the dates given above would require correction, to compensate for the effect of the current or electric shock to the needle of the galvanometer at the instant of charging, yet as such accuracy is not essential in this case, we may consider the results noted as giving a sufficient approximation thereto.

Reducing the charge for all the cables to an equal length of 328 feet, the following proportions are shown.

Gutta Percha.	No. I.	No. II.	No III.
140	115.9	102.5	146.3

It was of interest to ascertain the electro-static capacity, expressed either in absolute measurement or in microfarads; but not having at the time a graduated condenser available, the capacity of the gutta percha cable had to be determined by the formula

$$\frac{0,1876\ 9}{\log.\ D - \log.\ d}$$ microfarad for the nautical mile; in which D indicates the exterior diameter of the dielectric, and *d* the diameter of the conductor. The electro-static capacity of the 328 feet of gutta percha covered cable, worked out by this formula, was .0237 microfarad; from which it follows that the electro-static capacity of 328 feet of the new cables respectively in microfarads amounted to

Cable	No. I.	No. II.	No. III.
	.0181	.0164.	.0232

while these tests for capacity were being made, the water in which the cables were submerged was at a temperature of 19° 9' C. (67 Fahrenheit.)

An attempt was made to calculate the resistance of insulation by the loss of charge, but this was not successful, as after one minute of insulation the samples of the new cable charged did not show any noticeable loss, or at most, in some isolated cases, very little traces of loss; while, on the contrary, the wire covered with gutta percha showed in the same time a loss of 1-150 of its primitive charge. Leaving cable No. III insulated for 2 hours, 15 minutes, the loss has been shown as 1-40 of the charge. In order to fully comprehend the causes of these small losses in charging, we should take into consideration, in addition to the short lengths of the cables, the low battery power with which they had been charged. Taking 1.079 volts as the average electro-motive force of a Daniell's cell, the potential was only 5·4 volts, and the total charge for 328 feet in microfarads did not exceed for the

Gutta Percha	Cable No. I.	No. II.	No. III.
.127	.089	.091	.121

Resistance of Insulation.

The experiments already made showed that a very considerable resistance of insulation must be expected, larger even for the cables than for the gutta percha covered wire. Consequently the ordinary method of measuring resistance by the Wheatstone bridge could not be applied, and the method of substitution was determined upon. First there was introduced in a circuit a Daniell element or cell; the artificial resistance of 328,800 Siemens' units; and the galvanometer with a shunt of 1-999 of its resistance:—the mean deflection was 28·3 degrees of the scale. Disregarding the relatively insignificant resistances of the galvanometer and the battery, we may assume that the same deviation would be obtained by the galvanometer without shunt, by introducing in the circuit a resistance of 328,800,000 Siemens' units. The constant of the galvanometer having been determined, it was then possible to proceed to the measurement of the insulation resistances of the samples of new cable, and the gutta percha covered wire. These having been substituted for the artificial resistance for this purpose, the single Daniell cell was replaced by 150 similar cells, and the entire current was caused to pass through the galvanometer. The average deflections so obtained were as follows:

For Gutta Percha wire......................11.7 degrees.
" Cable No. I..............................9.3 "
" " " II..............................9.3 "
" " " III.............................9.7 "

The product 328.8 × 150 × 28.3 divided by the deflections gives in each case the resistance in millions of Siemens' units. In this manner we get as resistance of the dielectric:

For Gutta Percha wire .... 93,708 millions of S. U.
" Cable No. I.......................147,960 " " "
" " " II.......................147,060 " " "
" " " III......................143,028 " " "

or, reducing all the cables to a length of 328 feet:

For Gutta Percha wire................. 93,708 millions of S. U.
" Cable No. I.......................133,161 " " "
" " " II.......................162,756 " " "
" " " III......................113,028 " " "

The temperature of the water during these experiments was 10° C.

To remove all causes of inaccuracy the electromotive power of the 150 cells compared with that of the single cell should have been previously determined. The ratio between these two was certainly not strictly 150: 1, which would cause a slight modification of the factor 150. But this error of calculation is not important and may be overlooked. While a strictly accurate determination would vary the figures a little, it would not change the general impression which is obtained from the experiments with the cables, their comparison with gutta percha remaining the same.

Resistance of the Conducting Core.

The conductivity of the core was measured by the well-known Wheatstone bridge. The difference in temperature is explained by the fact that during the tests, the temperature of the bath was reduced for the purpose of other experiments. The results obtained were as follows:

Gutta Percha Wire.	10.5 C.	.07 Siemens Units
Cable No. I.	10.5 C.	10.93	"
" No. II.	9.5 C.	8.21	"
" No. III.	9.5 C.	8.21	"

and by reducing all the cables to 328 feet, length, respectively:

Gutta Percha Wire.	.07 Siemens Units
Cable No. I.	12.17	"	"
" No. II.	7.19	"	"
" No. III.	8.21	"	"

In the table at the end of this article the various results obtained in these tests are recapitulated, the data being based upon a uniform length of 328 feet for each sample tested.

An examination of this table will show that as regards electro-static capacity and insulation, the new cable gave better results than the gutta-percha covered wire, but these good qualities are somewhat offset by the comparatively considerable resistance of the conductor. This difficulty, however, is unimportant for short distances; for example, for lines in cities, lines through railroad tunnels, and other similar cases where resistance is of little consequence. In addition to the increased resistance of the conductor should be mentioned the special arrangement for the ends of these cables required to connect them with aerial lines. As the lead conductor is altogether too malleable to connect directly with a hard wire, a special ebony or ivory coupling should be made use of for the purpose of making the joints. This coupling, which has to be fixed on the lead wrapper, has inside a brass tube which serves the purpose of a connection between the two conductors.

With regard to the outer protecting wrapper or sheath upon which depends the duration of the cable itself, it certainly does not absolutely guarantee permanence; but it is claimed by the manufacturers that lead is not the only protecting material that can be made use of. For certain purposes it may do well enough, but in the majority of cases this protection should be strengthened and supplemented by either a coat of tar, inclosed by a tarred ribbon, or by the addition of a covering of iron wires.

In summing up the advantages and disadvantages of these new cables, especially taking into consideration the reduction of cost to be obtained, it seems to us that they are entitled to a thorough investigation and to be practically tried. They offer a better insulation than the other styles of cable; their flexibility admits of their following without difficulty the turnings and windings of an uneven road, and the outside covering may even be used as a return wire. For telephone communications, for instance, they are undoubtedly very suitable. Also in cases where by contact with air gutta-percha becomes deteriorated, the new cables may be substituted to the advantage.

74

A NEW KIND OF TELEGRAPH CABLE.

A COMPANY has recently been formed at Cortaillod, in Switzerland, for the purpose of manufacturing a new kind of telegraph cable, the conductor of which is formed of lead and the insulating material of a resinous or sulphurous substance, the whole being covered by a lead tube.

In spite of the slight flexibility of the insulating substance the new form of cable is very pliant, being by no means inferior in this respect to other forms; also the conductor rigorously preserves its

central position in spite of any bends which may be made in the cable.

In a recent number of the *Journal Télégraphique*, M. Rothen has given the results of some tests he has made of this form of cable.

Three specimens of this cable were experimented upon, the two first only differing from one another in their respective diameters, the insulating material being of a resinous nature. The third cable had an insulating dielectric of a sulphurous nature.

The lengths, weights, &c., of the cables were as follows:—

	No. 1 cable.	No. 2 cable.	No. 3 cable.
	Metres.	Metres.	Metres.
Length	90	110	100
	Millimetres.	Millimetres.	Millimetres.
Diameter of conductor	1·43	1·7	1·7
Exterior diameter of dielectric	2·9	3·7	3·9
Exterior diameter of protecting lead tube	4·8	5·9	6·3
	Kilogrammes.	Kilogrammes.	Kilogrammes.
Weight of 100 metres of cable	13·8	20·5	20·9

The cables before being tested were immersed in water for 5 days.

As a standard of comparison a gutta-percha covered copper wire 100 metres long was taken, the diameter of the conductor being 1·4 millimetres and the diameter of the dielectric 4·3 millimetres.

The tests were made with a battery of 150 Daniell cells.

The first tests made were for inductive capacity, the results being as follows:—

	No. 1 cable.	No. 2 cable.	No. 3 cable.
Capacity in microfarads per 100 metres ...	·0184	·0162	·0232

The capacity of the gutta-percha wire per 100 metres was ·0237 microfarads.

The insulation resistances of the cables measured by the ordinary deflection method were as follows:—

	No. 1 cable. Megs.	No. 2 cable. Megs.	No. 3 cable. Megs.
Insulation resistance in Siemens' units per 100 meters ...	133,164	162,756	143,028

The resistance of a similar length of the gutta-percha wire was 93,708 megs., the temperature of the tank in which the cables were immersed being 19° C.

The conductor tests gave the following results:—

	No. 1 cable.	No. 2 cable.	No. 3 cable.
Resistance of conductor in Siemens' units per 100 metres.	12·17	7·49	8·21
Temperatures	10·5° C.	9·5° C.	9·5° C.

The resistance of the copper conductor of the gutta-percha covered wire per 100 metres at 19·5° C. was found to be ·97.

If we compare these results by allowing for the varying diameters of the cables we get the following:—

	Insulation resistance.	Inductive capacity.	Conductivity.
Gutta-percha cable with upper conductor.	1·000	1·000	10·000
No. 1 cable	1·987	·558	·998
No. 2 "	2·208	·540	1·147
No. 3 "	1·817	·826	1·047

These results show that the three cables have an average specific insulation resistance of about double that of gutta-percha, whilst the specific inductive capacity of cables 1 and 2 is rather more than one-half that of gutta-percha. The conductivity of the conductor is extremely low, being only about $\frac{1}{10}$th that of copper.

THE Chilian fleet has destroyed the submarine cable off Arica. Telegraphic communication with Autofagasta is also interrupted.

June 79

By the conditions of our treaty with Afghanistan, a line of telegraph will be erected between Cabul and India, *via* the Khurum Valley.

75

PROGRESS IN SCIENCE AND THE ARTS.

General Science.

In the course of an editorial on the Brooks Underground Telegraph, concerning the merits of which we gave an account in last week's issue, the *Journal of the Telegraph* gives in its adhesion to the general principle of underground telegraphy in the following statement: "A thoroughly insulated and reliable telegraph cable, which shall supply the means of conducting telegraph wires underground in cities and under rivers and other bodies of water that must be crossed by the wires, has become a necessity." It then proceeds to give a cordial indorsement of the Brooks system as the best, cheapest, etc. Our contemporary is still disposed to confine the utility of the underground system of telegraphy to cities, in the face of the example of Germany. This partial concession, however, to the irresistible logic of events is somewhat inexplicable, in view of our contemporary's admission that "the Brooks cable can be put down at a relatively less cost than air-lines can be constructed (where a large number of wires is required), and the expense of maintenance will be but a small percentage of that of air-lines. It is estimated that the average yearly deterioration of air-lines is 10 per cent; but *these cable lines will be practically indestructible, and, once laid, can be relied upon indefinitely.*" [Italics are ours.—ED.] In the face of these admissions, and with the defects of the aërial system so obvious and notorious, the conservatism of our contemporary in limiting to the cities the utility of a system which it admits to be practically perfect, is incomprehensible.

Apropos of the Superiority of Subterranean Lines of telegraph, the Cologne *Gazette* further justifies our long-since expressed confidence in the system by the statement that the storms which have lately raged in Germany have demonstrated, in the most unmistakable manner, the fact that previous to the extended adaption of the underground plan, telegraphic communication was frequently interrupted throughout the empire with immense inconvenience. Since its introduction, in spite of snow and storm, not the slightest interruption has ever occurred in the telegraph service.

City Notes.

Old Broad Street, March 27th, 1879.

THE DIRECT UNITED STATES CABLE COMPANY.—The half-yearly general meeting of this company was held at the City Terminus Hotel, on Friday the 21st March. Mr. John Pinder, M.P., the chairman, presided, and in moving the adoption of the report, an abstract of which has appeared in *The Times*, after referring to the financial results of the half-year's working, which are given in the report, said the gross earnings, in spite of the general depression in trade, had increased by £5,700, being at the rate of nearly 7 per cent., as compared with the corresponding period of 1877. The total expenses showed a decrease of £3,300, equal to 13 per cent., due, however, principally to the comparison being made with the December half of 1877, in which period they incurred expenditure for repairs. Deducting this item, in order to make the comparison a fair one, the working expenditure had been slightly reduced. It would, however, have been very considerable but for the new charge for duplex royalty, which did not appear in the accounts of 1877. He then alluded with regret to the obstruction which the present Board had met with from interested parties, and said this had continued until the other day, when the arbitration was closed by the delivery of the award. The money for obtaining this must all come out of the shareholders' pockets, and it had been literally thrown away, for the award amounted to about what the liquidator offered to the dissentient shareholders—namely, £13 per share, but with interest, say £15. The dissentient shareholder put forward in his claim as the value of his interest the sum of £76,143—that was, he took his shares as worth £76 each, the par value being £20. The actual amount awarded to him was £15,000, or £15 per share. The expenses of the arbitration would not be far short of £10,000. They had heard lately of the attempt to get up an opposition company in France. The same parties, assisted by a French combination, were, he said, what he might term the promoters of this scheme. It had astonished him to find that French companies such as those who were taking an interest in this scheme should have looked so little into facts and figures. He had been to Paris accompanied by other gentlemen interested in Atlantic submarine telegraphy, and they had interviewed the leading men connected with those financial companies. He told those gentlemen that the Direct Company had many advantages in its greater security from its connexion with the the Anglo-American Company, and that in every sense it was a much more valuable property than their new cable could be, but that the shares of the Direct Company, at the time he was speaking to them, were at a discount of close upon 50 per cent. He pointed out that the company, if brought out, must of necessity come down to the same level, and that if they persisted in their scheme after this information the moment their cable was laid competition would arise—that a shilling, or probably a sixpenny tariff, must be adopted, and although there would be a diminution in this company's receipts, it would entirely prevent the new company from paying one shilling to their shareholders, and the result this company would look forward to would be that they would in time, if they chose, become possessed of the new cable at 30 or 35 per cent. of its cost. He pointed out to them that there was no necessity whatever for a new cable, seeing that the existing cables were equal to three or four times the amount of work now offered, and seeing that since the Anglo and Direct Companies had both applied the duplex principle, their carrying power had been very greatly increased. The result of the visit, which was three months ago, was no doubt to open the eyes of the financiers, who were still wisely hesitating. He was told that the *amour propre* of the French people must be satisfied, that the whole of this great telegraph enterprise centred in England, and that France should share it, although France contributed only about 11 per cent. of Atlantic traffic. He had always held that submarine telegraphy should have an international character, and with that view and in order to meet the French susceptibility, the Atlantic companies were prepared to establish a company in France, with a French representation, using the Brest cable for the scheme to work in harmony with the existing systems. The promoters of the new scheme said they had got a concession from the French Government. It had been stated that the head of the combination was to receive £20,000 for this concession with a permanent position as president of the company. He also understood that the gentleman who was to manage the company was to secure for himself a remunerative position, and that the financiers who were said to be backing it up were to receive a very large amount of money other than what was required for the construction of the cables. As to the concession, he might mention that there was already a concession from the French Government held by the Anglo Company, which gave them very important advantages, with a preference of all the French traffic, and this concession had still eleven years to run. He was anxious to obtain a sight of the new concession. He applied at the Government offices, but found for some reason, although one of the leading Ministers told him he saw no reason why a copy of it should not be given them, up to that moment they had not received a copy of it. He was told, however, by the same French Minister that it was merely a landing right, and that the French Government would be prepared to give such a concession to any respectable company who might ask for it. As to the amount of promotion money, so far as he could learn, the two cables for which they were asking subscriptions for over £2,000,000 might be contracted for that day for about

76

essots. When they had a surplus of revenue they would be in a position to pay a dividend on the ordinary shares. They could not prophesy when they would be able to pay a dividend on the ordinary shares—it depended entirely on their traffic. When the cables were laid down business was in a more active state in Peru than had been the case ever since, and the traffic had certainly not come up to the expectations originally formed of it, partly from this cause and partly from another cause not within their control—the interruptions to neighbouring lines. The steamer had made one voyage carrying water, and she had also been employed in carrying cargo and towing. She was fitted up and ready for employment in any of the ways stated in the report. She was an excellent vessel. All their cables were in working order, and the cable in store was in perfect electrical condition. They could not tell what effect the war between Chili and Bolivia would have on their traffic, but he thought he might say that for the present month it would have a very favourable effect on the local traffic. The debenture interest was 8 per cent. on £150,000. Any one could see what that amounted to, and the position of the ordinary shareholders as to dividend. Their expenses were excessively small, and it would be their policy to keep them down as much as possible consistent with efficiency. Mr. Gray remarked that the Company's cables extended from the capital of Peru, past Bolivia, on to the capital of Chili, Valparaiso, touching at various intermediate posts. Before war was declared they were asked to connect Autofogasta, one of the Bolivian ports. He then referred to the causes out of which the war arose, and afterwards stated that there would probably be one length, from Autofogasta to Iquique, through which no messages would go; but he anticipated a great local traffic. He felt satisfied that neither of the Governments would injure the cables, because in peace they derived such great benefits from them. In fact, the Presidents of Chili and Peru had told him that they would do all they could to preserve the cables. The report was then unanimously adopted. The other business was disposed of, and the meeting closed with the usual complimentary vote.

SUBMARINE CABLES TRUST.—According to the Report of the Trustees, the revenue for the year was £26,165, from which £1,890 was expended in the purchase of twenty certificates, and £2,000 has been deducted for expenses, leaving a balance of £22,275. Of this sum £10,362 has been applied to the payment of the coupons due on October 15th last, and the balance of £11,913 is carried forward. The amount required to pay the coupon on the 15th inst. is £10,362.

The Western and Brazilian Telegraph Company (Limited) notify that telegrams for Chili, Bolivia, and Peru are subjected to a scrutiny by the authorities in Valparaiso, and stopped or forwarded according to their discretion. The authorities in Valparaiso also intimate that no refund will be made for messages so stopped. This company likewise announce on April 25th, the repair of their Para-Maranham section.

In order to promote the carrying out of an arrangement concluded between the Telegraphic Administrations of Germany and Norway, a company was constituted on April 23rd, in the office of the United German Telegraph Company for the laying and maintenance of a cable between Germany and Norway.

Direct United States Cable Company (Limited). The Board of this Company have resolved upon the payment of an interim dividend of 5s. per share, being at the rate of five per cent. per annum, for the quarter ending March 31st last.

The following are the latest quotations of telegraphs:—Anglo-American, Limited, 55-55½; Ditto, Preferred, 84-85; Ditto, Deferred, 27-27½; Black Sea, Limited, —; Brazilian Submarine, Limited, 6½-6¾; Cuba, Limited, 8-8½; Cuba, Limited, 10 per cent. Preference, 15½-16½; Direct Spanish, Limited, 1¾-2¼; Direct Spanish, 10 per cent. Preference, 10-10½; Direct United States Cable, Limited, 1877, 10¾-11¼; Eastern, Limited, 7½-7¾; Eastern, 6 per cent. Debentures repayable October, 1883, 104-107; Eastern 5 per cent. Debentures repayable August, 1878, 100-103; Eastern, 6 per cent. A NEW KIND OF TELEGRAPH CABLE.

A COMPANY has recently been formed at Cortaillod, in Switzerland, for the purpose of manufacturing a new kind of telegraph cable, the conductor of which is formed of lead and the insulating material of a resinous or sulphurous substance, the whole being covered by a lead tube.

In spite of the slight flexibility of the insulating substance the new form of cable is very pliant, being by no means inferior in this respect to other forms; also the conductor rigorously preserves its central position in spite of any bends which may be made in the cable.

In a recent number of the *Journal Télégraphique*, M. Rothen has given the results of some tests he has made of this form of cable.

Three specimens of this cable were experimented upon, the two first only differing from one another in their respective diameters, the insulating material being of a resinous nature. The third cable had an insulating dielectric of a sulphurous nature.

The lengths, weights, etc., of the cables, were as follows:

	No. 1 cable.	No. 2 cable.	No. 3 cable.
	Meters.	Meters.	Meters.
Length	90	110	100
	Millimeters.	Millimeters.	Millimeters.
Diameter of conductor	1·43	1·7	1·7
Exterior diameter of dielectric	2·9	3·7	3·9
Exterior diameter of protecting lead tube	4·8	5·8	6·3
	Kilogrammes.	Kilogrammes.	Kilogrammes.
Weight of 100 meters of cable	13·8	20·5	20·9

The cables before being tested were immersed in water for 5 days.

As a standard of comparison, a gutta percha covered copper wire 100 meters long was taken, the diameter of the conductor being 1·4 millimeters and the diameter of the dielectric 4·3 millimeters.

The tests were made with a battery of 150 Daniell cells.

The first tests made were for inductive capacity, the results being as follows:

	No. 1 cable.	No. 2 cable.	No. 3 cable.
Capacity in microfarads per 100 meters	·0184	·0162	·0232

The capacity of the gutta percha wire per 100 meters was ·0237 microfarad.

The insulation resistances of the cables, measured by the ordinary deflection method, were as follows:

	No. 1 cable.	No. 2 cable.	No. 3 cable.
	Megs.	Megs.	Megs.
Insulation resistance in Siemens' units per 100 meters	133,164	162,750	143,628

The resistance of a similar length of the gutta percha wire was 93,709 megs., the temperature of the tank in which the cables were immersed being 10° C.

The conductor tests gave the following results:

	No. 1 cable.	No. 2 cable.	No. 3 cable.
Resistance of conductor in Siemens' units per 100 meters	12·17	7·49	8·21
Temperatures	10·5° C.	9·5° C.	9·5° C.

The resistance of the copper conductor of the gutta percha covered wire per 100 meters, at 10·5° C., was found to be ·97.

If we compare these results by allowing for the varying diameters of the cables, we get the following:

	Insulation resistance.	Inductive capacity.	Conductivity.
Gutta percha cable with copper conductor	1·000	1·000	10·000
No. 1 cable	1·987	·558	·908
No. 2 "	2·208	·510	1·147
No. 3 "	1·817	·826	1·017

These results show that the three cables have an average specific insulation resistance of about double that of gutta percha, while the specific inductive capacity of cables 1 and 2 is rather more than one-half that of gutta percha. The conductivity of the conductor is extremely low, being only about 1-10th that of copper.

77

The Brooks Underground Telegraph Cable.

THE Brooks underground telegraph system, the details of which, though familiar to telegraphic engineers, have received but little publicity, appears during the past two years to have been quietly establishing its claims as a simple and effective solution of the problem of underground telegraphy; and, from the developments of the last few days, it is very probable that it may soon come into general use, in this country at least.

The system of Mr. Brooks differs from all others in the fact that the material employed for maintaining the insulation of the line is a liquid—paraffine oil—which is known to possess, for this purpose, qualities of the highest order; and in laying it the wires—thirty, forty, or fifty, as may be required—covered with cotton binding, are placed in an iron pipe, conveniently located, and the pipe line filled with oil—allowed to run in until full, the maintenance of the supply being assured by providing an elevated vessel of the material at intervals, so that a constant pressure will be kept within the pipe. This is practically all there is about it, and its extreme simplicity appears to be not the least of its merits, as one of the great objections advanced by the advocates of the post system has been the great expense of laying and maintaining underground lines.

Upon the question of its practical working we now have very good testimony, and this, we are pleased to be able to state, is unqualifiedly favorable. The first line constructed upon this system, and which was actually put to work, was laid about two years ago. It was about a mile in length, and is reported to have been successful beyond all expectations; its insulation at the end of two years having improved rather than deteriorated. The next experiment was made at the instance of the P. W. & B. Railroad, a submerged line being laid across the Schuylkill. It gave good results, and has ever since been in operation, its insulation, like that of its predecessor, having increased. Since that time a number of lines have been laid; one connecting the switch-boxes with the signal tower of the Pennsylvania Railroad west of the passenger depot in West Philadelphia; another across the Christiana and Brandywine creeks at Wilmington; and two across the Hackensack river, at Jersey City. At the present time negotiations are pending, according to our authority, for connecting Camden with Philadelphia by a line across the Delaware, for the laying of a line across the Hudson at New York, and for a line between New York and Philadelphia.

The advantages of a meritorious and reliable system of underground telegraph over the old aerial system have been so often pointed out in the *Journal* that their repetition here would be useless. We have simply to record the progress of events from week to week, a task in the case of this item that we perform with peculiar gratification.—*The Engineering and Mining Journal.*

78

THE NEW GERMAN-NORWEGIAN CABLE.

At a recent conference held in Christiania, it was agreed between the representatives of the German Empire and the two Governments of Norway and Sweden, that Germany shall, at her own cost, lay down a three-wired cable from Romoe, an island off the west coast of the Schleswig and the Norwegian coast, at a point between Mandal and Arendal. From that place the Norwegian Government undertakes to carry the line on so as to connect it with the whole Scandinavian telegraph system.

The cable is estimated to cost two million crowns, about £95,000, and it remains in the possession of Germany who has also to repair it at her own cost. It is further specified to be laid by October 1st of this year. Norway is to put up a new wire from the landing point to the capital, together with a cable-house. As to the correspondence to be sent through this new cable, it is resolved upon that all telegrams from Norway to Germany itself, are to be transmitted by it, and at least three-fifths of all the other traffic with foreign countries, excepting the Russian, English and Danish, unless it should prove more expensive to use the new route than the other existing ones. On the other hand, Germany has power to forward all messages she is able to collect and forward them through her new cable, unless the sender has indicated another route.

Besides this new cable Norway has three ways for her telegraphic communication abroad, viz., through Sweden and by cable from Trelleborg to

* Blakey Bros. and Emmott.

Rügen, from Arendal to Fredericia in Denmark (cable to Hirtshals), and from Ekersund to Peterhead in Scotland, this last being reserved for her English traffic. If the new line is slower than the existing ones, Norway has a right to forward her telegrams by the best route. Besides, Norway may become free to forward her telegrams by any way she chooses by purchasing one-half of the cable, or by giving notice to the convention at the end of 20 years. Norway has a very large correspondence with all sea-faring countries because of her extensive mercantile navy, and it is said that the correspondence of Germany with Norway is second only to her correspondence with England.

Hitherto Germany has been obliged to send her telegrams to Norway through Denmark and Sweden, a course which has been manifestly irksome to her, owing perhaps in part to the uneasy political relations between her and the Danes. In 1878 she tried to effect an arrangement similar to that which has just been concluded, but Norway refused because of the great expense which she was then asked to share. The new scheme will, of course, deprive Denmark of the traffic which formerly passed over her lines between Germany and Norway; and, seeing that the present means are ample for the necessities, the Danes are disposed to regard the new act of the German Government as proceeding from a desire to have a line of their own, in case of war between Germany and their own country. This idea was also expressed in the Norwegian Storthing or Parliament, when the Government asked for the money for the new line.

The Underground Telegraph in Germany.—In continuation of our late reference to the progress of the system of subterranean telegraphs in the German empire, we may note that an underground cable now connects the cities of Berlin, Halle, Leipsic, Cassel, Frankfort, Mayence, Mannheim, Carlsruhe, Rastadt, and Strassburg: another line connects Berlin, Magdeburg, Brunswick, Hanover, Münster, Düsseldorf, Elberfeld, and Cologne: another connects Berlin and Hamburg, with branch lines to Kiel and Cuxhaven; to Bremen and Emden, thus joining the North Sea cable communicating with England and America. The money lately voted (1,830,000 marks) by the Reichstag for the further extension of the underground telegraph, it is said, "will be employed in connecting the towns and harbors along the Baltic, and for the furtherance of commerce and coast defense." On the lines already completed, the sum of 18,000,000 marks ($4,500,000) has been expended. May 79

The Extension of the Pneumatic Tube System, which is at present going on in this city, will, when completed, connect the offices of the *Herald, Times, Tribune, World, Sun,* and *Staats-Zeitung* with the Western Union Telegraph building. At present the W. U. Telegraph Company has two lines of pneumatic tube in operation, one to 134 Pearl street, and the other to the Stock Exchange.

May 79

Brooks' Insulated Underground Cable.

A thoroughly insulated and reliable telegraph cable, which shall supply the means of conducting telegraph wires underground in cities, and under rivers and other bodies of water that must be crossed by the wires, has become a necessity. The rapid increase of wires, especially in large cities, is already rendering further construction a difficult problem. Within the last two years this increase has been greatly stimulated by the demand for special wires and telephone communication, and the practicable limit for suspended wires in many places has very nearly been reached. It is probable that the time is near at hand when additional wires must be put underground, in cities at least, and eventually all wires in such places will be put out of sight, and where they can be better protected than is now possible. This would have been done before but for the fact that no system had been devised which filled the requisite conditions.

Much time, labor and money has been expended in the efforts to devise and perfect such a cable, but until the underground cable telegraph invention of Mr. David Brooks, of Philadelphia, was devised, the difficult problem has not been satisfactorily solved. This cable seems to have the requisite elements, and very thorough tests of it during the last three years have fully met the expectations of the inventor and others who have known of them and were interested in the result. The core of this cable may be of any number of copper wires, the superior conductivity of the copper compensating for the small size of the wire necessarily used when a large number of wires are to be made into one cable.

The advantages of this system, especially when a large number of wires and a perfect insulation are required, will be readily seen. Any required number of wires can be laid within a moderate compass. As they are underground or under water, they are not subject to the interruption and damage inseparable from air lines. Storms of wind, rain and sleet, which are so damaging and destructive to ordinary telegraph lines, have no effect upon these cables,

hers, if its value and usefulness were properly appreciated its membership would be doubled at least. It has been and is most judiciously and economically managed, and its reliability and permanence are assured by its accumulated fund. The payments required to be made are assessed in such a manner that any single payment is small in amount, and therefore does not bear heavily upon even those of moderate salaries and income. Under such circumstances it would seem as though all persons engaged in the telegraphic service, who had others dependent for support in whole or in part upon them, would, if eligible to membership, at once seek admission.

Those of us who were in the service before the organization of the Association, well remember the constant applications made for contributions to bury the dead, or relieve the living who were left helpless by the death of some telegrapher. It is a much more effective way of making such provision, to join the Association. The amount collected by subscription in individual cases is necessarily small and insufficient, but a thousand dollars affords substantial relief, and at a time when it is most needed. Besides there is the satisfaction of knowing that it is not charity asked for or received, but a provision for which a consideration has been paid, and a matter of right.

There is nothing novel in the views above presented, but they may serve to call the attention of some to the advantages offered by the association, and induce them to provide against the evil day when those dependent upon them shall find their supporter taken from them.

It might, perhaps, be found practicable either by extending the scope of the present Association or by the organization of one specially for the purpose to make further provision in cases of sickness or disability of telegraph employés. This seems to be a desirable end to be accomplished, and it may be well to agitate the matter with a view to ascertaining the opinions of the telegraphers upon the subject. Perhaps, if such an arrangement were properly started and under proper management, the managers of the Western Union Company would aid and favor it as they have done the Mutual Benefit. The idea is at this time merely thrown out for consideration. Whether anything shall come of it or not we have the Mutual Benefit, and are assured of effective assistance for those dependent upon us in case of death, if we choose to avail ourselves of its privileges.

MEMBER.

A Suggestion for Improvement of Cabinet Batteries.

Objections to Underground Telegraph Lines

MR. W. H. PREECE, electrician of the Postal Telegraph Department, in a recent lecture before the Society of Arts, said there are 10,000 miles of underground wires in Great Britain, but the known facts which tell against the extension of the underground lines are: There is an increase of three or four times in the cost; their capacity for carrying currents is reduced three or four times; the gutta percha coating is attacked not only by rats and mice, but very largely by an insect called the *tempeltonia crystallina*, and is also influenced by a fungus. May 79

79

The New German-Norwegian Cable.

AT a recent conference held in Christiania, it was agreed between the representatives of the German Empire and the two Governments of Norway and Sweden, that Germany shall, at her own cost, lay down a three-wired cable from Romoe, an island off the west coast of Schleswig and the Norwegian coast, at a point between Mandal and Arendal. From that place the Norwegian Government undertakes to carry the line on so as to connect it with the whole Scandinavian telegraph system.

The cable is estimated to cost 2,000,000 crowns (about $460,000), and remains in the possession of Germany, who has also to keep it in repair at her own cost. It is further specified to be laid by October 1st, of this year. Norway is to put up a new wire from the landing place to the capital, together

Telegraphy in South Australia.

THE number of local messages transmitted in South Australia in 1878, was 376,244. Of intercolonial messages 99,170 were sent, making a total of 475,414, for which cash to the amount of £32,425 was received in the colony. The rate in 1877 was rather less, as the corresponding number of messages in 1877 was only 408,477, and the cash receipts £27,717. There has been not only a large augmentation in the number of messages, but an increase also in their average length. The enlargement in the business between the Australian colonies and Europe is particularly striking, the increase in the number of

The South African Cable.

THE telegraph cable to connect the European and Asiatic telegraphic systems with Cape of Good Hope will be 4,000 miles long, extending from the Red Sea cable, at Aden, around Cape Gardaful and along the east coast of Africa to Port Natal, where it will make a junction with the present land line to Cape Town. The cable will be laid along the coast, the depth of water being moderate along that side of the continent, and the facility for repairing possible breakages has been carefully ascertained. The cable will touch at Zanzibar, Mozambique, Sofala, Delagoa Bay, and thence to Durban, as the submarine terminus, from which point the land telegraph becomes available to complete the circuit to Cape Town. The cost of constructing and laying the cable is estimated at $7,500,000. The line from Durban to Zanzibar is to be finished in July, and the whole cable by the middle of November. May 79

The Proposed French Atlantic Cable.—Failure to obtain Subscriptions to the Stock.

June 79

The combination of French financiers which is seeking to place these shares on the public have, if we are correctly informed, been very considerably disappointed in the result of their appeal to the patriotism and *amour propre* of the French people. These ove their country well, but they are evidently not disposed to invest their money in an undertaking more than doubtful in its results, and at prices, by comparison with an existing enterprise of the same character, rather more than twice its actual value. Not only are the shares which are offered for subscription in the new company twice the market value of the shares in the Direct Cable Company, but they are offered at about 30 per cent. above the price which has been actually paid for them by the French syndicate, who are seeking to relieve themselves of the liability which they have incurred. One-half of the nominal capital required for the new company has been, it is said, taken by a group of financiers at 25 per cent. discount; the public are invited to subscribe for the remainder at 27½ per cent. above the price at which they have been thus taken by the syndicate. There is yet another interesting fact in connection with the prosecution of this undertaking, formed to secure for France what is termed her "telegraphic independence." The promoters of the scheme are to receive 1,000 shares of 500 fr., or £20,000, as a bonus, and they are to receive, in addition, 5 per cent. of the whole profits after the ordinary shareholders have received 5 per cent. as their proportion.

The bourgeoisie and the small capitalists of France whom it is sought to attract to this scheme have failed, in spite of all the efforts of the group of financiers, to see the advantages which are to be obtained from securing independence of telegraphic communication for France. The profits to be derived from making and laying the cable will go to a German manufacturing firm carrying on its business in London; the loss which will inevitably occur upon the enterprise will fall upon French citizens; the only benefit which will be obtained, that of temporary cheaper telegraphic communication with America, will be enjoyed exclusively by the great capitalists and financiers of Paris and elsewhere, who may have the advantage of the reduction of rates which competition with the Anglo-American Company will surely effect. The Anglo-American Company have already absorbed the French cable laid from Brest a few years since, and secured at a discount of about 50 per cent. the Direct United States Cable, which was to have accomplished so much for the cause of telegraphy, civilization, and the commerce of the world. They will as surely succeed in getting possession of the latest "want of the age," and they will obtain it on their own terms. They have four cables already at work, and they will, acting, and very properly so, in the protection of the interests of the shareholders, reduce the rates to a point at which it will be impossible for the new company to secure a profit, and then the end will be, as in every other case since the world began, that competition will end in combination, and the shareholders of the new French company will be fortunate indeed if they escape with a loss less severe than that which has befallen the unfortunate victims of the Direct United States Cable enterprise.

We believe, as already stated, that the response of the French people to the new scheme has been an all but complete failure. Already overtures have been made to the Anglo-American Company for terms. The French syndicate are alarmed at the extent of the liabilities which they have incurred, and contemplate with serious apprehension the future calls which may be made upon them for carrying out this wholly unnecessary and doubtful enterprise. The Anglo-American Company have made their arrangements for establishing a company having its headquarters in Paris. It will take over the original concession granted by the French Government, and the Brest cable, which was the fruit of that concession, will be handed over to this new company, with all its rights and privileges and all its business connections in France, England, and America. France will thus secure the object which the promoters of the new company profess to have in view—viz., "the telegraphic independence" of the country. What more is necessary? One thing is necessary, that is, that funds should be provided to give activity to the works, and employment for the telegraph ships of the contractors. The appeal for these funds has been met with a prompt, decided, and unequivocal answer from the French public. The money must be provided, therefore, by the French syndicate, or the proposed scheme must end, as others have done, in an arrangement with the Anglo-American Company.—*The Railway News.*

Underground Telegraphs.

ARTICLES of incorporation of the Brooks Underground Telegraph Company have been filed in the County Clerk's office, New York. The route of the line is from the corner of Broadway and Dey street to West street, thence to some prominent point on the North River, across the North River to Jersey City, thence to Philadelphia, and thence to various points in the United States, following the route now occupied by the Western Union Telegraph Company. The capital stock is fixed at $200,000, divided into 2,000 shares of $100 each. The right to increase the capital stock to $1,000,000 is reserved. The shareholders of the company are David Brooks, of Philadelphia, 500 shares, and Anson Stager, of Chicago, and Norvin Green, of this city, 750 shares each. The company is incorporated for fifty years, beginning May 21, 1879, and terminating May 21, 1929.

A Pacific Cable.

THAT eventually a cable will be laid from the Pacific coast to the Sandwich Islands, Japan and China there can be no doubt. When this line is established the telegraphic circuit of the world will be complete. Mr. Cyrus W. Field holds an exclusive concession from the government of the Sandwich Islands for such a cable, as was announced at the recent celebration of the twenty-fifth anniversary of the organization of the company which resulted in laying the Atlantic cable. Concessions will also be obtained from Japan, and probably from China. We understand that the organization of a company to carry out this project is proposed, and that Mr. Field has agreed to contribute $100,000 in cash as a subscription to its capital stock. It is expected that capitalists upon the Pacific coast, who will naturally feel a pride in the establishment of such a line, will also contribute liberally to give the project a start and carry it through. The business interests of the coast would be greatly facilitated by such a connection.

Mr. Field sailed for Liverpool on the 21st ult. in the Cunard steamship *Bothnia*, and during his sojourn in England will make such investigations in regard to the manufacture and laying of a Pacific cable as will enable him and his associates to act understandingly in furthering the proposed enterprise. No steps will be taken towards organizing a company until after the return of Mr. Field. It is to be hoped that sufficient encouragement will be extended to insure the construction of the line at no distant period.

Underground Telegraph Lines.

THE subject of underground telegraph lines, especially for large cities, is attracting much attention from the public and press. We print extracts from several leading newspapers, with accounts of interviews with leading telegraph officials on the subject, which will be read with interest. If it shall be conclusively demonstrated, as there is good reason to believe it will be, that the invention of Mr. Brooks of a cable especially adapted to such lines has obviated the difficulties which have hitherto prevented carrying city wires beneath the streets, much relief will be afforded to telegraph companies as well as the public from a serious and constantly aggravated difficulty. There is apparently no limit to the demand for wires for telegraphic purposes, and to adequately provide for it a change in the construction of city lines is rapidly becoming a matter of absolute necessity.

June 79

UNDERGROUND TELEGRAPHS IN CITIES.

THE *New York Tribune* in an article on proposed changes in city telegraph lines in connection with the Brooks underground cable has the following:

General Stager, by whom the patent of the Brooks cable was purchased, said recently: "I regard the new plan as entirely feasible, and I believe it can be used with regularity and certainty for short distances. It has been in use in Philadelphia for a distance of two miles for two years. We have laid out three routes for this city along the line of the elevated railways. There are 16,000 poles now standing on this island, and our engineers estimate that when the new system is in operation there will be only 1,600 poles left standing in the cross-streets. If the city gives us the use of the streets we may be able to shorten the routes by placing the trunk lines of wires under ground instead of along the elevated railway structures. We shall offer the city the advantage of putting all its police and fire alarm wires under ground. Submarine cables at the most have only seven wires. There will be twenty wires in each of our tubes, and for telephone purposes probably fifty. Chicago has a line laid containing 100 wires which works splendidly. We have in one sense of the word begun work, as we are making machinery to prepare the wires. We do not propose to break ground until the system is perfected, which will take fully three months.

"There is no positive arrangement with the Western Union Company as yet for the employment of this system, further than a general agreement that if it can be shown to be serviceable and valuable it will be used. I propose to put it in operation alongside the wires now on poles, and to rely on its success for its adoption by the company." June 79

When asked if he anticipated any difficulty in securing the privilege of excavating in the streets, General Stager said: "There has been a desire for a long time that our poles be taken down. Our answer has been: 'Show us a system by which we can construct a subterranean telegraph and we will cheerfully do so.' We offered to accept any plan that would work, and I have scores of drawings and models, none of which met the emergency until the Brooks patent was tested. I believe that the authorities and the general public will cheerfully yield the privilege of the streets if we will remove the unsightly miles of wire which now obstruct the thoroughfares. It is very doubtful if permission to erect telegraph poles in the large cities will be granted to any corporations in the future. In Germany the rubber insulated underground wires have been abandoned, as it is asserted that the soil, mice and insects destroy the insulation and in time break the circuit. By the new system of insulation of the wires, the iron tubes and the oil exclude moisture, insects and mice. A new era in the adaptation of telegraphy in large cities and across streams may be said to have been begun."

82

the ebonite, and wider spaces than usual betwee the binding screws.

Mr. Conrad W. Cooke exhibited Sykes' electri lock and block system for railway working, and a ingenious new galvanometer of his own inventio for demonstrating the internal current in a voltai cell. The plates of the cell under test are immerse in the liquid at the upper ends of a curiously blown glass tube, which would have the form of a U tub were it not that the bent portion is drawn out fin and coiled into a spiral, in the middle of which i hung a galvanometer needle. The internal curren passing through the liquid in the glass spiral tells it presence by deflecting this needle.

Cowper's Telegraphic Pen; Crossley's Microphon (described in our issue for May 1); Firnhaber's patent synchronous electric clocks, exhibited b Messrs. Edmundson & Co., were also to be seen a work.

Messrs. Elliott Brothers maintained their hig reputation as electrical mechanicians by a fine dis play of galvanometers, keys, and resistance coils and Mr. Groves exhibited a finished specimen o the Induction Balance of Professor Hughes. A audiometer was also shown by Messrs. Krohne and Lesemann.

The India-Rubber and Gutter-Percha Telegraph Works Company displayed many specimens of their reason for withdrawing ... believed that all the difficulties will be readily over-come. The greatest objection to the terminus is that, owing to the frequent thunder-storms in the summer, the land wire thence is very frequently out of repair. An alternative route, via Pretoria, is now in course of construction.

The agreement between the Government and the contractors requires that the cables shall be capable of transmitting 14 words a minute; and that the company shall, save in case of *force majeure*, have the portion of the cable between Durban and Zanzibar, laid and open for the transmission of messages on or before the 31st day of July, 1879, and the portion between Zanzibar and Aden, on or before the 31st day of December, 1879. The companies are entitled to connect the cable with all lines of telegraph in the colony of Natal at such points as shall be approved by the Natal Government, and with all land and submarine telegraphs having stations or termini at Aden. The Eastern Telegraph Company agrees to maintain and provide a suitable and properly equipped steamship in the Red Sea or Indian Ocean for the purpose of making repairs to the said line of submarine telegraph between Durban and Aden, it being understood and agreed that such steamship may be employed for repairs to other lines owned or worked by that company. All Government messages (whether Imperial or Colonial) are to have priority to all other messages, at rates equal to one-half of those charged to the general public. The stations on the line are to be open from eight a.m., until eight p.m., and throughout the night, when there is any traffic to forward, or when specially required by her Majesty's Government (whether Imperial or Colonial) to be open. It is provided that the rates to be received by the company owning or working the line for messages (other than Government messages) transmitted thereby, exclusive of charges payable to other companies or administrations, shall not exceed the following; that is to say—between Durban and Aden, and vice versa, 5s. a word; between Zanzibar and Aden, and vice versa, 4s. a word; between Aden and London, and vice versa, by any of the lines of the said Eastern Telegraph Company, a total charge of 3s. 9d. a word. And the said rates shall not be increased without the

[From the *New York Herald*.]

Brooks' Underground Telegraph Cable.—Poles to Disappear from the Thoroughfares and Housetops of Cities.

It is proposed to carry the telegraph wires of the city underground by means of insulated iron tubes, and eventually remove from the public thoroughfares and housetops all the unsightly poles or network of wires which have been gradually accumulating, especially since the introduction of the telephone, until they have grown to be a nuisance. In this city are 16,000 telegraph poles. When the new system is fully introduced it is thought that not six hundred poles will remain in this city, and these will be chiefly required to convey transverse lines from the main trunks running lengthwise of the island, as near as practicable to its "backbone." The trunk lines, it is thought, will be upon the avenues on which the elevated railroads are built. It is now under discussion whether the tubes will be ultimately carried on the beds of the elevated roads or buried under the streets. The great danger of interruption of the whole telegraphic system by reason of a fire or other serious accident is a strong objection urged in some quarters among scientific men against the use of the elevated railroad structures for the purpose of conveying the tubes.

In discussing the scheme last evening, with a map before him showing the various Western Union offices of the city marked upon it, President Green, of that corporation, said to a *Herald* reporter: "It is the purpose to do away with the pole lines in large cities, but to what extent the exchange will be made in New York is as yet not fully determined. The Brooks Company has had the friendly assistance of the Western Union Company for the purpose of its introduction in all large cities where there is an aggregation of wires at any single point. To what extent good pole lines will be removed for the purpose of transferring wires to underground tubes, is a question that has not yet been fully decided upon, as the expense attending the change has not been provided for. It is probable, however, that no more pole lines will be erected in cities. As fast as poles rot away or wear out the underground system will be substituted."

"Have you the right to go under the streets?"

"The charter of the company gives it the power to go over or under water or underground. The company must ask permission, however, to raise the pavement, and in doing so interfere as little as possible with the traffic of the streets. The new invention is considered a grand stride in practical telegraphy. It is the first practical and economical solution of the difficulties and annoyances of occupying poles and housetops with telegraphic and telephone wires."

"When will the work begin?"

"The down-town wires will be changed first. The company has but just been organized. Some tubes will be laid this summer. Wherever the wires are the most numerous and the poles are the most perishable the changes will be effected first. There are 16,000 poles in the city. Of this number the Western Union and its allies own about ten thousand. With the wires carried up the island in tubes, either on the bed of the elevated railroads or sunk under the earth, less than six hundred poles will be necessary to convey the transverse lines to the various intermediate offices on the island. Fires, for instance, would cripple the use of the tubes if affixed to the elevated roads. Underground they would be free from that danger at least. The rapid accumulation of telephone wires, especially in cities, has made the necessity for a change imperative."

Tel. Journal. July 1. 1879

A PACIFIC CABLE.—That eventually a cable will be laid from the Pacific Coast to the Sandwich Islands, Japan and China, there can be no doubt. When this line is established the telegraphic circuit of the world will be complete. Mr. Cyrus W. Field holds an exclusive concession from the government of the Sandwich Islands for such a cable, as was announced at the recent celebration of the twenty-fifth anniversary of the organization of the company which resulted in laying the Atlantic cable. Concessions will also be obtained from Japan, and probably from China. We understand that the organization of a company to carry out this project is proposed, and that Mr. Field has agreed to contribute 100,000 dollars in cash as a subscription to its capital stock. It is expected that capitalists upon the Pacific coast, who will naturally feel a pride in the establishment of such a line, will also contribute liberally to give the project a start and carry it through. The business interests of the coast would be greatly facilitated by such a connection. Mr. Field sailed for Liverpool on the 21st ult. in the Cunard steamship *Bothnia*, and during his sojourn in England will make such investigations in regard to the manufacture and laying of a Pacific cable as will enable him and his associates to act understandingly in furthering the proposed enterprise. No steps will be taken towards organizing a company until after the return of Mr. Field. It is to be hoped that sufficient encouragement will be extended to insure the construction of the line at no distant period.—*The Journal of the Telegraph*, U.S.

AUSTRALASIAN TELEGRAPHY.—Of the 588 miles of electric cable to be carried out by the steamship *Scotia*, in order to continue the line of telegraph already complete from Penang to Malacca, and thence laid nearly as far as Singapore, the end was wound on board on the 25th ult., from the Telegraph Construction and Maintenance Company's Works at Greenwich. This fine vessel of 4,600 tons, formerly a paddle ship in the Cunard fleet, and since altered to a double screw, with an additional deck, measures 379ft. in length, her beam being 48ft. She has engines of 500 horse-power, and her speed is 13 knots. A large company of guests, including many representatives of foreign countries, who are assembled to take part in the International Telegraph Congress, went down from Westminster Pier on a river steamer, and boarded the *Scotia* during one of the heaviest showers of the day.

The following are the final quotations of telegraphs for the 26th ult.:—Anglo-American, Limited, 55-55½; Ditto, Preferred, 84½-85½; Ditto, Deferred, 27-27½; Black Sea, Limited, —; Brazilian Submarine, Limited, 6¾-7¼; Cuba, Limited, 8¼-8¾; Cuba, Limited, 10 per cent. Iron July 5 1879

beginning the first Wednesday of September...

A TELEGRAPHIC CABLE.—*The Railway World*, of Philadelphia, says:—Arrangements have been almost completed for the laying of a cable of the Brooks underground telegraph across the river Delaware, from Walnut Street wharf to Camden. The cable will be composed of forty wires, of which ten are telephonic and the others Morse wires. The former are about the thickness of ordinary sewing thread, and the telegraphic wires are about as thick as druggist's twine. They will be inclosed in a welded iron tube, having an inch and a half diameter inside. This tube will be laid along the bed of the river on the course of the present cables of the Western Union Telegraph Company, and will be carried over Smith's Island, below the surface of which it will be sunk a depth of 2 feet.

THE ENGINEERING AND MINING JOURNAL.

JULY 2, 1881.]

See Notes

Underground Telegraph Wires.—Our article on the Philadelphia Mining Stock Market announces the fact that Philadelphia will be the first city in the United States to make a trial of the underground telegraph. The Common Council has granted to the National Underground Electric Company permission to lay its conduit for electric conductors under certain streets. The number of telegraph wires in all parts of the city makes it absolutely necessary to adopt that measure. The enterprise is reported to be in the hands of those who are fully capable of making it a success; after which, the company will extend its operations to New York, Boston, and other large cities. Mr. Fawcett, the Postmaster-General, in replying to a question recently asked in the British House of Commons, has communicated some very interesting facts. London, in proportion to its size, has suffered more from the dangers of overhead wires than any of the large towns and cities of Great Britain. Some of the streets are literally cobwebbed with wires crossed and recrossed in every conceivable direction, the danger to pedestrians and others in high winds or during extremely low temperatures having become a very grave matter. Mr. Fawcett says that the post-office authorities are endeavoring to reduce the mileage under the old system as rapidly as possible. The progress made is shown by the facts that in 1877 there were 1720 miles within a radius of four miles of the general post-office, whereas now the mileage is only 500, and the underground wires have increased from 3350 miles to 4808 miles in the same time. The tube manufacturers, founders, and those engaged in kindred industries will be especially benefited by the general adoption of the system.

Il n'est pas superflu de rappeler l'expression brutale dans sa naïveté.

Voici ce que dit l'académicien Babinet à la page 19 du VIIᵉ volume des ÉTUDES SUR LES SCIENCES :

« *Après avoir constaté* que tous les télégraphes maritimes à *longue portée se trouvent* maintenant *hors d'état de fonctionner*, j'ai discuté les *difficultés* qu'il faudra surmonter pour la pose d'un télégraphe sous-marin unissant le Nouveau Monde et l'Ancien. Parmi ces difficultés, il y a la nécessité d'un calme de plusieurs jours pour déployer un fil de plus de mille lieues de longueur.

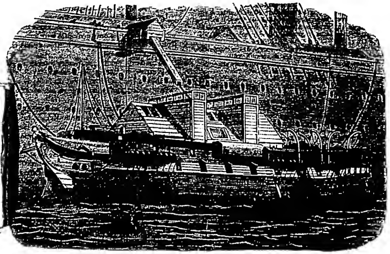
« Il y a le poids de ce conducteur qui fait la charge de deux grands vaisseaux qui se séparent au milieu de l'Atlantique, voguant l'un vers l'Europe, l'autre vers l'Amérique ; cette charge est au comble, même avec un fil gros comme le petit doigt.

« Il y a la profondeur de 7 kilomètres, à cause de laquelle le conducteur peut à peine supporter son propre poids avant d'arriver au fond de l'Océan.

« Il y a la crainte que les inégalités du sol de la mer et les actions mécaniques n'amènent la rupture du conducteur.

« Il y a la prompte détérioration de ce conducteur par l'action corrosive de l'eau salée, jointe à un prix de revient de 18 millions de francs.

« Il y a enfin un fonctionnement d'une efficacité très-problématique, puisqu'une dépense d'environ cinquante mots au moyen du Transatlantique qui a fonctionné peu de jours, a exigé trente heures pour sa transmission. Ce n'est pas tout que d'établir une communication entre deux points éloignés l'un de l'autre d'un hémisphère entier, il faut encore que le nombre des signaux échangés produise une véritable correspondance. Or, deux mots par heure ne font pas une correspondance suffisante. »



Un chaland anglais apportant au *Great Eastern* le premier câble transatlantique français.

Ce précieux morceau, corroboré par d'autres ultérieurs, a été rédigé en 1860 et réimprimé sans en changer un l en 1863, comme si l'auteur tirait gloire des arguments qu'il avait publiés.

Ce livre se vend actuellement chez Gauthier-Villars. Il a été cliché pour ne point être épuisé. L'éditeur se réserve les droits de poursuivre les contrefacteurs.

La collection des *Études sur les Sciences d'observation et leurs applications pratiques* a eu tant de succès qu'elle a été continuée sous le même titre par un auteur non moins célèbre que M. Babinet, quoiqu'il ne fasse point encore partie de l'Académie.

Si l'on veut bien prendre la peine de lire ce curieux factum, on reconnaîtra que les hommes d'initiative et de pratique se sont chargés de fournir une réponse catégorique et complète aux objections qui dans le plupart des affaires scientifiques auxquelles il s'est trouvé mêlé.

L'année même de la mort de Babinet, une Compagnie française entreprenait la pose d'un câble transatlantique destiné à faire concurrence à la ligne anglaise.

Le *Great Eastern* venait à Brest pour procéder à cette gigantesque opération.

On croyait alors qu'il n'y avait que le navire géant qui pût servir à la pose du câble monstre. Comme il ne pouvait se mettre à quai de l'usine de Greenwich, où il avait été construit, on fut obligé d'employer pour le transporter à bord le secours de pontons.

L'Illustration du temps a conservé la trace de la manière dont s'est opéré le transport comme beaucoup d'autres précautions intermédiaires devenues superflues.

THE TELEGRAPHIC JOURNAL AND ELECTRICAL REVIEW.

VOL. VIII.—No. 170.

CABLE PROPERTY.

THE past year has been a very advantageous one for the telegraph companies, at least, if we may judge by the considerable increase of the traffic receipts. In nearly every instance an addition to revenue has resulted on the year's business as compared with the previous year. The Anglo, Brazilian Submarine, Cuba Submarine, Direct Spanish, Direct United States, Eastern, Eastern Extension, the Great Northern, and The Submarine Companies all mark important increases. The returns of the West Coast of America and of the Western and Brazilian we have not at hand, whilst those of the West India and Panama Company show a slight decrease.

We do not think we shall be considered optimists when we assert that probably at no time in the comparatively recent history of submarine telegraphic enterprise has the future appeared more hopeful. Indeed, so rapidly does the business of the companies promise to extend that were it only possible to obtain greater permanency for the ocean threads, there would soon scarcely be found a better paying class of investment.

As, however, that lasting cable has not yet been proved to have been discovered, it is for the time necessary to pay particular attention to the accumulation of the respective reserve funds.

At what amount each should stand cannot well be told by any beyond the directorate or the scientific staff of any company, and not even by them, with any degree of accuracy.

This must depend on the nature of the ground over which the cable passes, the type of cable laid, the length of time it has been down, the amount of repair which has from time to time been effected on it, and also on so many considerations that it is impossible, as we before said, to estimate at what exact sums the reserve funds should stand; but, speaking generally, it will, we believe, be found that they are yet by far too meagre.

It has, therefore, been with considerable satisfaction that we have noted the constantly progressive increase of receipts, as it will enable the companies to obtain that position of security without which their properties seem destined to remain at their present low prices.

Another source of increasing value is to be found in the additions to existing systems, which should prove of pecuniary advantage to the parent stems, even though those additions may not be in themselves paying concerns. This would, of course, only be the case where the added but non-paying line was owned by a separate company. But where it is so, every extension of a system must render the pre-existing portion of that system of greater value than before.

On taking together the amounts of the receipts of twelve companies for 1879, and comparing them with those of 1878, we find the former exceed the latter by about £215,000, and this on a return of about £2,000,000. In the case of one of those companies whose returns we have not, namely, the Western and Brazilian, we hope that with Sir Edward Watkin's well known energy and talent it will now emerge from the cloud which has seemed to hang over it, and we trust that a similarly happy outcome may be found for the sorely tried West India and Panama Company.

Were it not for the competition which the American Cable Companies will have to meet, there seems every reason to think that the augmented receipts would not only be maintained but even still further increased—particularly as trade will, in all probability, more generally improve during the present year; but if sixpenny word tariffs are to prevail, immense loss must ensue to those companies engaged in the strife. It is to be hoped so suicidal a policy will not obtain, or, if it does, that it will be but of short duration.

In closing these few desultory remarks, we take this opportunity of congratulating the directorates and staffs generally, on the improved outlook, and of expressing the wish, that this time next year it will be our pleasing task to refer to submarine cable property as not only well paying, but also as well secured.

ON SOME OF THE EFFECTS PRODUCED BY AN INDUCTION COIL WITH A DE MERITENS MAGNETO-ELECTRIC MACHINE.

The South African Cable.

A PARLIAMENTARY paper has been printed giving the agreement May 9, 1879, entered into by the Government with the Telegraph Construction and Maintenance and Eastern Telegraph Companies for establishing telegraphic communication with the South African colonies. The route decided upon, as already announced, was the one submitted by Mr. Pender on behalf of the two companies—from Aden to Natal, touching at Zanzibar, Mozambique and Delagoa Bay. The Government subsidy was fixed at £35,000 per annum. The tariff was fixed at 4s. a word between Aden and Zanzibar, and 5s. a word between Aden and Mozambique, Delagoa Bay or Natal; and neither of these charges nor the present charge of 3s. 9d. a word between Aden and London are to be altered without the concurrence of the official director. The cables are to be capable of transmitting fourteen words a minute. The Governments of Victoria and New South Wales concur in the postponement for a short period of the duplication of the Australian line, in order that the cable already manufactured for that purpose might be used in laying the Cape line.

The New French Atlantic Cable.

THE *Bulletin Financier* calls the attention of subscribers to the Pouyer-Quertier shares to the fact that the official quotation promised from the very beginning is not coming forward, and apprehends that it will not be obtained soon, or else the promoters would not allow the shares to decline 20 francs below the price of issue in a moment of furious rise, where there is even demand for all sorts of rubbishing low-priced stocks. Our contemporary expresses the opinion that the protest made concerning the landing of the cables in the United States has acted as an impediment with our official brokers; but the *Bulletin* gives this as a private opinion, and adds that the stock has not been applied for, and that the members of the syndicate begin to grow rather fidgety. Besides, the second instalment is due, and, in the absence of official quotation and of any market, for what is done in the shares bears a most limited character, it is not easy to sell out. What the situation will be when the third instalment falls due is evident. It leaks out now that the applicants rather subscribed with the view of pocketing a premium in reward of their patriotism than with that of becoming serious shareholders. The case is not without danger, especially if any difficulty arose respecting the landing of the cable.—*Paris Bourse.*

ENGINEERING NEWS.

Tribune Building, New York City.

GEO. H. FROST, PROPRIETOR.

SATURDAY, SEPT. 3, 1881.

WE received the following note from Prof. P. H. Philbrick, dated Iowa City, Aug. 23, 1881: "I hope Mr. E. J. Ward will be able to continue his articles on 'Wind Pressure.' The matter has been much neglected and slighted in the past."

TO THOSE INTERESTED IN WATER-WORKS.

Owing to the author's absence from this city on professional duty the manuscript of "The History and Statistics of American Water-Works" has not reached us in time for this week's issue. We take advantage of the space thus afforded us to call the attention of those officers of water-works who have not yet responded to the requests for information regarding their works to the scope and character of Mr. Croes' book, and we desire to again urge them to furnish the memoranda required to make this history complete. It is intended that it shall be complete, and the information will be obtained to make it so, in one way or another. The simplest and easiest way will be for those who possess all the data to contribute them as early as convenient.

We are fully aware of the fact that superintendents of water-works are overwhelmed with circulars from all quarters asking for elaborate information on every conceivable subject connected with the construction and management of works of water supply. If they reply, their answers are either buried in the files of some little company's office, or printed in a report of some obscure town which reaches only a small proportion of those who are interested in the matters treated. The work which we are now publishing will, to a very large extent, obviate the necessity for the asking of such questions. It will be a practical manual of water-works construction and management, treating not of theoretical questions, but giving the results of actual experience, without attempting to excuse blunders, explain away failures, extol successes, or expiate on the merits of any particular system of construction, supply or management.

The idea of this book grew out of the effort to procure a general description of the works of water supply in America for the Centennial exposition in 1876. The American Society of Civil Engineers exhibited then a very creditable collection of plans, models and statistics, gathered for the purpose by Mr. Croes, who had charge of that branch of the work of the society's Centennial Commission. The catalogue of that exhibit contained the first list of American towns having water-works ever published. It was necessarily incomplete, owing to the short time allowed for its compilation, but even then comprised the names of all the works of any importance, and seventy-five per cent. of all which were then in existence.

In the following year, Mr. Edward Prince, C. E., of Quincy, Ill., published a list of water-works which has been enlarged from time to time through his earnest and persistent efforts to procure information. He has kindly placed at Mr. Croes' disposal the catalogue of reports and documents obtained by him, and such brief abstracts of them as had been prepared by him.

The publication of Mr. Croes' book began in the issue of ENGINEERING NEWS for March 5, 1881. Up to this time, statistical and historical sketches of eighty-one water-works have appeared, as follows, the towns being at first arranged according to their population by the last census, an arrangement afterwards abandoned on account of the difficulty of procuring the very latest reports in time:

Town.	Population.	Page.	Date.

While this list includes but a small portion of the whole number of water-works in the country, the descriptions of the works contain already a more valuable collection of facts relating to water-works construction and maintenance, the accidents and failures of ill-considered and carelessly constructed structures, the cost of construction and maintenance, and the revenue derived from water supply, than any other single publication ever issued. To make this record complete is the author's intention and our desire. A large amount of material is now on hand for this purpose. We *want everything*, and we therefore again ask every superintendent, engineer, manager and commissioner to send us reports, facts and figures.

The sketches, comprising the first part of the book, are arranged according to the following order, for each town: Location and topography of town, date of first settlement and of incorporation, date of construction of water-works and description of same, both old and new: sources of supply, filters and wells, pumping engines or reservoirs, supply mains or conduits, reservoirs, distribution, sizes and kind of pipes; number of hydrants, taps and meters, cost of construction and maintenance, and the revenue, both total to date and particularly for the year 1880; organization and officers of works, daily average consumption. Failures and accidents of all kinds are specially noted. Hereafter tabular statements of the chief points of interest will be given, including duty and cost of pumping engines.

Many officers of works have contributed descriptions of their works admirably fitted for insertion in the book, without material change, and the compiler's labors are, of course, greatly lessened by such kind assistance. The interest taken in the work is exhibited in the most gratifying manner by correspondents from all parts of the country, and the author and the publisher are alike encouraged to carry out the design to its full extent.

SUBTERRANEAN CONDUCTORS.

The problem of providing some effective plan for placing electric wire underground is, at the present time, attracting much attention. In all large cities the network formed by these wires interferes most materially with the efficient working of the fire departments, and as it is exposed to every atmospheric change it is damaged, and in its damage hurts the interests of the entire community.

The number of these wires is rapidly increasing, caused by the extension of the telegraph, telephone and electric lighting systems, and a device is imperatively demanded by which the present practice may be done away with.

We have received a pamphlet from Mr. Stephen Chester, C. E., which discusses the question: Are subterranean telegraph lines practical? After citing the various evils consequent to the system now in vogue, the author enumerates the principal objections alleged to exist against the use of subterranean conductors, by reputable experts, as follows:

"First.—All underground conductors are relatively very much more costly than are air lines.

"Second.—Breaks in wires or imperfections in insulation cannot be readily located, and the repairs of the same would be expensive and difficult.

"Third.—No material yet used for insulation of subterranean wires has been satisfactorily proved to be indestructible, nor do any of such materials when buried in the ground retain their integrity nearly so well as do submarine conductors.

"Fourth.—The obstacles impeding the efficient use of long, continuous conductors, because of '*Induction*' and '*Retardation*,' are vastly greater in buried wires than they are in aerial lines of corresponding length."

These allegations are met by the statement that the subterranean conductors, referred to as enormously costly, have consisted of copper wires, first covered with an expensive insulating substance such as vulcanized rubber, kerite or gutta-percha, and still further protected by being inclosed in metal tubes.

In all the many uses to which insulated wires have been applied, it has been requisite that the insulating covering should be impervious to water, flexible, and of such tenacity and durability as not to be liable to injury in the handling necessary to place them in position, nor to deterioration in conducting or insulating qualities by reason of exposure to heat or cold, air or water, etc.

Up to the present time all compositions uniting these qualifications have been expensive, and only readily applied to very flexible and therefore small wires. The wires used have been mostly of copper, as this metal possesses a conducting power much greater than iron for equal sizes.

As such insulated conductors are relatively much more expensive than those used on aerial lines, and possess but little relative tensile strength, and the insulating covering is not of a character that will stand rough handling or abrasion without injury, they have but seldom been placed under ground or water without being further protected by some other non-insulating but hard and tough covering. This adds greatly to the original cost. In order to

1876

UNDERGROUND LINES AND PNEUMATIC TUBES IN EUROPE.

Under date of March 6th, a circular letter was addressed by Mr. George B. Prescott to the different telegraphic administrations in Europe, in which information was requested concerning the number of miles of underground lines operated by each, their location, the method of insulation, and the length of time they had been operated; also as to the extent of the pneumatic tube system for transmission of messages. The following replies have already been received:

SWITZERLAND.

SWISS CONFEDERATION,
DIRECTION OF TELEGRAPHS,
BERN, 1st *April*, 1876.

GEORGE B. PRESCOTT, *Electrician Western Union Telegraph Company:*

SIR.—We hasten to give you the information about the cables in Switzerland, requested in your favor of March 6th.

The Swiss cables are of four classes, viz., Under-lake cables, cables on the dangerous passes of the Alps, to avoid the avalanches, cables in tunnels of railroads, and cables in cities.

The under-lake cables are laid only in the Lake of Constance, where, by mutual consent with the Bavarian and Wurtemberg administrations, we have one-wire cables between Romanshorn and Nonnenhorn, and between Romanshorn and Friedrichshafen. One-half only of these cables belong to our administration, and in the following statement of the length of our entire cable system, only one half of their total length is included. These cables were constructed by Felton & Guilleaume, in Cologne, and are similar to the underground cables.

Our lines cross the Alps in several places, either to make communication between the different sections of Switzerland situated on both sides of the Alps, or to connect Italy with Switzerland and the neighboring countries. These lines in some cases are at a height of 2,400 metres (7,900 feet) above the level of the sea, and consequently reach the region of eternal snow. Owing to avalanches, these passes are dangerous, yet they cannot always be avoided; consequently, at these places we have constructed underground cables, especially on the Simplon, on the Saint Gothard and the Fluela. The cables used came from Rattier & Co.'s works in Bezons, near Paris. Each cable is composed of three or five wires, according to the number of the wires in the line. Each copper core consists of seven wires of one-half millimetre (one-fiftieth of an inch) twisted together.

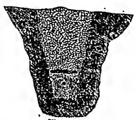

Figure 1.

This wire is covered by a double guttapercha sheath, and wound around the guttapercha is a hemp covering, soaked in Chatterton's compound. The different cores of the cable are united in one single strand, which is enveloped in three layers of hemp soaked in Chatterton's compound, the first and last in the shape of ribbons, and the one in the centre in the shape of wires or strands. The whole is enclosed in a leaden tube hermetically closed.

These cables are buried in the ground to a depth of from two to three feet. The cable is surrounded by sand, and covered with flat stones, and the trench is filled up with ordinary gravel (Fig. 1). In some places, especially in Fluela, it has been found necessary to dig the entire trench in the rocks.

In all the railroad tunnels which are about 300 metres (1,000 feet) and upward in length, the overground wires have been replaced by cables of three, five, or seven wires. If there are more than seven wires in a line, two or more cables are used. Some of these cables are of the same manufacture and come from the same works as those of the Alps. Still, in the Cornaliaz, Vanderens, St. Maurice, Mayats, Haut de la Tour, de la Combe, Mont Lagne, des Loges, de la Zimmeregg, and Bözberg tunnels, we have made experiments with the other cables manufactured in the St. Aubin works in Switzerland. The insulating material of the latter cables is purified asphalt. The construction of the copper cores and the outside leaden tube is similar to that of the Rattier cables.

With regard to the manner in which the cables in the tunnels are laid, we have used different systems. In some tunnels they are buried in the ground, in a similar manner to those across the Alps. In some places they have been fitted with cement in a groove in the rocks, in other places trenches of cement blocks have been used, as illustrated in Fig. 2; but latterly they have almost all been laid in saturated wooden tubes fixed on the walls of the tunnel, about 1½ metres (5 feet) from the ground (Fig. 3).

Fig. 2.

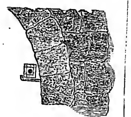

Figure 3.

We have used, with regard to cities, underground cables in every instance where it was difficult to reach the stations by means of aerial lines, or where the airlines would have looked unsightly in the streets through which they had to pass. There are cables laid in the following cities: Geneva, Lausanne, Bern, Zürich, Schaffhausen, Winterthour, Altorf, and St. Gall. With the exception of Schaffhausen, all the cables laid in the cities are manufactured at Rattier & Co.'s works, and are of the form heretofore described. In Schaffhausen we have made use of a cable made by the India-rubber Company in Silvertown (England). This cable differs from those made by Rattier mainly by the fact that the leaden tube is replaced by a tarred hempen sheath.

The cables in the cities are sunk into brick trenches, or in the sewers, or in Zores-iron tubes. We have no testing boxes, the portions of line not being long enough to make the experiment necessary.

91

The following is a list of all our cables and wires, their length, and the date when laid:

1. *Submarine Cables.*

PLACE WHERE BUILT.	LENGTH IN FT.		WHEN LAID.

Altdorf.	874	4,018	1873
St. Gall.	328	10,196	1866

NOTE 1.—This is only one-half of the entire cable.

2.—The cable, being laid in 1863 near the mouth of the Rhine, in the lake, has been damaged by pebble stones.

It was found necessary to take it up in 1866, and to lay it farther from the mouth. In 1869 and 1870 it had to be removed farther from the mouth.

3.—Partly laid in 1866, partly in 1872.

The entire length of all our cables is 33 English miles, that of all the wires in the cable tubes separately 213 miles.

You want also to know the length of the overground lines. We do not know whether you want to know the length of the wires in the cities or those in the entire system. The length of all the wires in our system is 9,575 miles, but the length of the wires only in the cities is pretty hard to give. Often it is hard to tell where the city ends, and the country commences.

With regard to the duration of our cables it is very difficult to give you any definitive answer. The majority of the cables have not been laid long enough to give, as yet, any conclusive results. The cable from Romanshorn to Nonnenhorn had to be repaired several times, owing to pebble stones, coming from the Rhine, as we have mentioned before.

The actual cables in the Cornaliaz, Vanderens and St. Maurice tunnels are the second cables which

92

have been laid in the tunnels. The first did not last for more than two years. They were cables insulated by means of asphalt, and manufactured in the St. Aubin's works. The cable of Neuchatel, laid under unfavorable circumstances also is suspended, the leaden tube being assailed both by gas and rats. A cable on the St. Gothard has considerable defects, probably caused by a defective laying. The other cables are in good condition, and do not give rise to any complaint, but it may be possible that one of the conducting wires is not as perfectly insulated as it was when laid.

The cables are crossed by comparatively speaking strong currents. The effects of charging and discharging, and of induction of one wire on the other are not felt, the cables being too short.

All the cables are shielded from the influence of atmospheric electricity by means of special lightning arrestors.

Pneumatic tubes are not used in Switzerland.

Hoping that this will be the information required, we beg to assure you of our profound respect.

The Director of Swiss Telegraph,
F. VEY.

NORWAY.

ROYAL TELEGRAPH OF NORWAY,
CHRISTIANIA, *29th March*, 1876.

GEORGE B. PRESCOTT, ESQ., *Electrician of the Western Union Telegraph Company:*

SIR,—I beg to acknowledge receipt of your honored letter, dated 6th this month, and have the honor to inform you that underground telegraph wires are not in use in this country. The strength of climate and the rocky ground will generally be a serious objection for applying underground wires to any extent in this country; and, in fact, we have so few wires that we find no serious objection over to towns to go over the houses.

I have the honor to be, Sir,
Your Obedient Servant,
C. PIERSON.

ITALY.

MINISTRY OF PUBLIC WORKS,
FLORENCE, ITALY, *26th March*. 1876.

MR. GEORGE B. PRESCOTT, *Electrician Western Union Telegraph Co.:*

SIR,—In answer to your letter of 6th inst., I beg to inform you that we do not make use of any underground wires nor of any pneumatic tubes, and that our system now contains 45,677 miles of aerial or overground wire.

Accept the assurance of my distinguished consideration.

The General Director,
E. D'AMICO.

ROUMANIA.

MINISTRY OF THE INTERIOR,
GENERAL DIRECTION OF TELEGRAPHS AND POSTS.
BUCHAREST, *March 27th*, 1876.

MR. GEORGE B. PRESCOTT, *Electrician W. U. Telegraph Company:*

SIR,—I have the honor to acknowledge the receipt of your letter of March 6th, and beg to give you the information asked for.

1. We have no underground lines as yet, but in the city of Bucharest they are going to be built in the course of this year. The length of the cables when laid will be 1½ miles. There will be three cables of seven wires, and two others of one wire each, in all a length of wire of thirty-six miles.

The cable has been constructed by the India-rubber Guttapercha and Telegraph Works Company of London, and consists of two guttapercha layers, and a stout wrapper of galvanized iron rods. The cable will be buried under the sidewalk in wooden tar-covered boxes, one yard deep.

2. With regard to the overground lines, we have in our entire country a length of 2,347 miles of poles, and 4,223 miles of wire.

I hope very soon to be enabled to send you a statement of my administration for 1875, in which you will find all the details, which will be of interest to you.

Please accept the assurance of my profound respect.

The Director General,
G. LAHOVARY.

BAVARIA.

KINGDOM OF BAVARIA,
MUNICH, *March 30th*. 1876.

MR. GEORGE B. PRESCOTT, *Electrician W. U. Telegraph Company:*

SIR,—Your letter of the 6th inst. is duly received. I beg to answer as follows:

We have underground lines only in a few of our larger cities, also submarine cables at Lake Bodensee connecting the Bavarian station Linden with the Swiss station Romanshorn, and at Lake Tegernsee with Gmund. The first-named are cables with from seven to eight wires, the last each of one wire. The total length of the underground lines is thirty-two miles, and the total length of the submarine cables eighteen miles.

The underground lines are, as has been above said, in use mostly in our larger cities, where reaching telegraphic offices could only be done with much difficulty by aerial wires. Such underground lines are:

(a) At Munich, firstly, to connect the Central Station, situated in the Telegraph building (*Bahnhofplatz*), with the branch offices, situated in the center of the city; and secondly, to connect this station with all land lines running together at the Central Railroad Station. The first connection consists of a cable nearly one mile in length, with eight wires; the latter of seven cables with seven wires, each of them 416 feet long, and of a similar cable 561 feet long.

(b) at Augsburg, where the connection of the Telegraph Office with the land lines is made in two different ways, by means of three cables, each of seven wires, about 416 feet long, and three others, each of 1,650 feet length.

(c) at Nurnberg. The underground cable here is only needed for a short distance, viz., to overcome the obstacles offered in a large open and much frequented place before reaching the telegraph station; five cables are in use here, each of them measuring 765 feet, and ending in 35 city lines, mounted on double-poles.

All our cables, both submarine and underground, are bought from the Telegraph Cable works of Felton & Guilleaume at Cologne on the Rhine. Each wire of the cable consists of three copper wires, twisted together, and three-one hundredths of an inch thick; they are enclosed with a concentric layer of the purest India-rubber. This India-rubber has twenty-two-one hundredths of an inch diameter, and in cables of 7 wires twenty-eight-one hundredths of an inch; the insulated wires are covered with a tarred hempen layer; in cables with more than one wire the spaces between the insulated wires are also filled up with hemp.

The outside covering of the one wire cables consists of 11 galvanized iron wires one-tenth of an inch thick; in cables of 7 wires, of 16 such galvanized iron wires sixteen-one hundredths of an inch thick.

The underground cables are covered with asphalt, and sunk about 3½ feet into the ground. The 8 wire cable, laid in 1856 at Munich, has worked perfectly since, and the India-rubber just as flexible as ever; the other cable at Munich has been in use since 1871; the cable at Augsburg from 1870, and that of Nurnberg from 1872.

The connecting of the branch office, Munich (Post Building) with the Central Station (Telegraph Building) is projected, but not yet started.

Very respectfully, Yours obediently,
GUMBART.
Secretary to the General Director of Telegraphs.

AUSTRIA.

MINISTRY OF COMMERCE,
VIENNA *April 6th* 1876.

GEORGE B. PRESCOTT, *Electrician Western Union Telegraph Company:*

SIR,—In reply to your favor of 6th March last, I beg to answer your questions for information about our underground lines and pneumatic tubes as follows:

1. *Underground and Submarine lines.*

After an experiment made as early as 1850 and 1851 to construct underground lines of any considerable extent, which resulted in failure, owing to the very defective technical knowledge of construction, our administration has preferred to build air lines, and now only construct underground lines when overground lines are absolutely not allowed.

The length of the system in Vienna is 1,617 feet, and consists of twenty cables of seven wires; the line in Brünn has a length of 1,574 feet, with six wires; the line in Prague 1,476 feet, with nine cables of seven wires.

The first mentioned of these three lines was constructed in the Fall of 1873; both of the others are only recently made.

All the cables used hitherto were made by Felton & Guilleaume in Cologne on the Rhine. Each line consists of a three-wired copper string covered with two layers of Chatterton's compound, and two layers of guttapercha, all the wires are twisted to one single string, covered with a layer of tarred hemp, and protected by an armor of 18 galvanized iron wires of ¼ inch diameter. In Vienna the cables are buried 6 feet deep in a wooden tube, the tube being filled with a mixture of tar and bituminous lime. In Brünn and Prague, it is only at particularly dangerous places, that an outside protection of a similar kind is given. The connecting of the cable with the line is done in a little pavillion, where a lightning arrester is placed between the cable and the air line, and where, also, any examination of the separate wires can be made.

Of 140 under ground wires of the city lines in Vienna up to the present time, not a single one has suffered any injury or weakening of its electrical capacity. Besides the cables for the city lines, there are in Austria, along the coast of the Adriatic Sea, only marine lines, with an aggregate length of 96 miles, to connect the Dalmatian and Istrian Islands with each other and with the mainland. Usually Hooper's India-rubber cables are used for this purpose. The copper strand consists of three wires of about one thirtieth of an inch in diameter, and with Hooper's insulating material has a thickness of ¼ of an inch.

This is provided with a tarred hemp covering and an armor of galvanized iron wires, which for the coast cables have a diameter of one-fifth of an inch, and for deep sea one-sixth of an inch. They also receive a coating of Clark's compound for protection against the corrosive action of salt water. The connecting of underground with overground lines

The Director of Swiss Telegraph,
F. VET.

NORWAY.

ROYAL TELEGRAPH OF NORWAY,
CHRISTIANIA, 29th *March*, 1876.

GEORGE B. PRESCOTT, Esq., *Electrician of the Western Union Telegraph Company:*

SIR,—I beg to acknowledge receipt of your honored letter, dated 6th this month, and have the honour to inform you that underground telegraph wires are not in use in this country. The strength of climate and the rocky ground will generally be a serious objection for applying underground wires to any extent in this country; and, in fact, we have so few wires that we find no serious objection even in towns to go over the houses.

I have the honor to be, Sir,
Your Obedient Servant,
G. PIERSON.

ITALY.

MINISTRY OF PUBLIC WORKS,
FLORENCE, ITALY, 26th *March*, 1876.

MR. GEORGE B. PRESCOTT, *Electrician Western Union Telegraph Co.:*

SIR,—In answer to your letter of 6th inst., I beg to inform you that we do not make use of any underground wires nor of any pneumatic tubes, and that our system now contains 15,677 miles of aerial or overground wire.

Accept the assurance of my distinguished consideration.

The General Director,
E. D'AMICO.

ROUMANIA.

MINISTRY OF THE INTERIOR,
GENERAL DIRECTION OF TELEGRAPHS AND POSTS.
BUCHAREST, *March* 27th, 1876.

MR. GEORGE B. PRESCOTT, *Electrician W. U. Telegraph Company:*

SIR,—I have the honor to acknowledge the receipt of your letter of March 6th, and beg to give you the information asked for.

1. We have no underground lines as yet, but in the city of Bucharest they are going to be built in the course of this year. The length of the cables when laid will be 1½ miles. There will be three cables of seven wires, and two others of one wire each, in all a length of wire of thirty-six miles.

The cable has been constructed by the India-rubber Guttapercha and Telegraph Works Com-

this serves to deliver the messages which ar[e] outside, of forwarding the dispatches receiv[ed] various Telegraph and Post Offices to the Telegraph Station, and to forward pneumati[c] between the City and its suburbs.

The entire system of tubes has an exte[nt] miles, and consists of a closed circuit with sev[en pneu]matic stations, also three single branch lines [..] one connects with the circuit in station I., t[he] in station II., so that altogether there are te[n pneu]matic stations in operation.

The line of tubes consists of wrought ir[on] 16¼ feet long, and 2¼ inside and 3 inches diameter. The single tubes are provid[ed] soldered and properly fitting flanges, which [..] ed in the middle by means of a screw, [..] additional caoutchouc packing ring having [..] ed there.

The tubes laying in curves are previously cold, bent to the required radius (minimum of [..] and buried an average depth of 3¼ feet in the [..] at the deepest points cast-iron supports are [..] as to let off the water condensed in the tubes.

The propelling power for the entire system [is fur]nished by two horizontal engines of respect[ively ..] and 12 horse power, which are set up in Sta[tions ..] and V. Each of these machines sets a coupl[e of] pumps for condensing and evacuating purp[oses in] motion, by which the air in 12 wrought iro[n reser]voirs becomes respectively compressed and [..] The cubic contents of the six reservoirs for co[mpress]ed air amounts to 380 feet, and of the six re[servoirs] for rarified air 295 feet. Four of these reserv[oirs are] put up in Station I., four in Station II., and [..] Station V.

The reservoirs of Stations I. and II. are fed [simul]taneously by the machine of Station I., and [for this] purpose, between the Stations I., and II. in a[ddition] to the pneumatic tubes, properly speaking, a [..] tube conduction of 1½ miles in length is [..] same material, and according to the same sy[stem] above described. The length of this doub[le con]duction is not taken in account, when summ[ing up] the aggregate extent of our system of pne[umatic] tubes. The over pressure in the compressio[n reser]voir usually amounts to 60 or 70 centimetres [..] 27½ inches) mercury, whilst in the other re[servoirs] the air is rarified at an aggregate pressure of [..] centimetres (12 to 15¾ inches).

The pneumatic apparatus of the ten stati[ons are] very similar to those which are made use of [in the] Paris system; its construction allows the con[nection] of the tubes leading to the next station either [forward] or backward alternately according to requi[rement] and the movement of the pneumatic train t[hrough] the whole of the tube system, hence follows, a[lternate]ly, either under the over pressure of the com[pressed] air against the atmospheric or under that of [the at]mospheric against the rarified air.

The pneumatic train in the closed circuit [consists] of some seven boxes with one piston. The [..] boxes are made in one piece of wrought al[..] steel, and are closed by means of a leather [..] They will hold from 20 to 25 messages or letter[s. The] train, consisting of seven boxes and piston, [weighs] from 7 to 9 pounds, and runs with an averag[e speed] of 1,100 yards a minute. At present the pne[umatic] tubes in Vienna are operated only between 8 [A.M.] and 9 P. M., so as to have a train from the

Mining & Sc. Press July 19 1879

THE NEW TRANSATLANTIC CABLE.—The cable steamer, *Faraday*, left Millwall at an early hour on Monday, and during the forenoon was safely moored abreast of Messrs. Siemens' works at Charlton. The *Faraday* is a powerful steamer of 4,000 tons, built at Newcastle in 1874 for Messrs. Siemens, and designed specially for laying cables. In the course of the afternoon she was surrounded by barges; those on the outside supplying her bunkers with coal, and those next to shore being employed in passing the cable into the steamer's tanks. The new company, the official style of which is, "La Compagnie Française du Télégraphe de Paris a New York," has opened offices in London for the transaction of executive business at 100 and 101, Gresham-house, Old Broad street. The *Faraday*, having on board the shore end and the Brest-Scilly section of the new cable, was cleared at the London Custom-house on Tuesday night for New York, and sailed for Brest the following morning. Her departure had been delayed, the wet weather having interfered with the work of coiling the cable in the bunkers.—*London Iron, June 21st, 1879.*

Mining & Sc Press July 19

THE SOUTH AFRICAN CABLE.—The telegraphic cable to connect the European and Asiatic telegraphic systems with the Cape of Good Hope will be 4,000 miles long, extending from the Red Sea cable, at Aden around Cape Guardafui and along the east coast of Africa to Port Natal, where it made a junction with the present land line to Cape Town. The cable will be laid along the coast, the depth being moderate along that side of the continent and the facility for repairing possible breakages has been carefully ascertained. The cable will touch at Zanzibar, Mozambique, Sofala, Delagoa Bay, and thence to Durban as the submarine terminus, from which point the land telegraph becomes available to complete the circuit to Cape Town. The cost of construction and laying the cable is estimated at $7,500,000. The line from Durban to Zanzibar is to be finished in July, and the whole cable by the middle of November.

Hardware July 1879

Telegraph Wires.—American cities are insisting upon underground telegraph wires, and this has occasioned a demand for a new kind of wire. Into glass tubes made in 14-foot lengths decarbonised steel wire is inserted. The glass tubes are then encased in a prepared iron pipe, and the whole heated in a furnace to a welding heat, which reduces the size and makes a solid mass of the iron, steel, and glass. It is claimed that this makes a conductor not only durable, but perfectly insulates it, and renders it proof against the influence of induced currents. Hardware July 1879

Telegraphic Journal July 15 1879

THE FRENCH ATLANTIC CABLE.—Some 345 knots of the Brest to Nova Scotia section of this cable have been successfully laid by the *Faraday*, which has returned to Brest after buoying the sealed end at Scilly.

LEAKAGE FAULTS IN CABLES.—In the *Philosophical Magazine* for July, there is an interesting mathematical paper on this subject by Mr. Oliver Heavyside.

94 Operator Aug 15 1879

Operator Cable Dividends. Aug 15 1879

The fourth ordinary general meeting of the Direct United States Cable Company was held in London, August 1st. From the report it appears that for the half-year the revenue, after deducting out payments, amounted to £87,706 3s. 2d.; for the corresponding period of 1878 the amount of revenue, after similar deductions, was £79,852 11s. 5d. The working and other expenses (exclusive of cost of repairs), interest on loan, and income tax, etc., amounted for the half-year to £20,523 5s. 10d., leaving a balance of £67,182 17s. 4d. as the net profit for the half-year. In the corresponding half-year of 1878 the expenses and payments above mentioned (also exclusive of cost of repairs) amounted to £20,065 17s. 9d. The cost of repairs for the half-year amounted to £8,965 9s. 11d.

Three quarterly interim dividends of 1¼ per cent. each, amounting to £45,532 10s. 0d., have been declared and paid at the usual times during the financial year, and a final dividend of 5s. per share was declared at the meeting, making, with the three interim dividends, 5 per cent. for the year, being a total distribution of £60,710. £34,756 4s. 3d. was added to the reserve fund, thereby increasing it to £100,000. £2,345 1s. 5d. was also carried forward to next account.

At a meeting of the board of directors of the Anglo-American Telegraph Company, held in this city July 11th, it was resolved (after reserving £17,500 for the renewal fund) to declare an interim dividend, for the quarter ending June 30th, of 1¼ per cent. on the consolidated stock, and 2½ per cent. on the preferred stock, both free of income tax. This leaves an estimated balance of £10,000 to be carried forward to next quarter's account.

The agreement with the Dominion Telegraph Company of Canada, referred to in the last report, has been completed, and came into operation as from the 1st January, 1879.

The particulars of the Award in the Arbitration between the Liquidators of the Old Company and Mr. Leoffler, were fully stated at the ordinary general meeting on the 21st March last.

The break in the Company's main cable which occurred on the 4th January last, was repaired on the 20th March, and the interruption on the 12th February last of the short section was repaired on the 22d April. Both sections of the cable are in good working order.

Telegraphic Journal Aug 1 1879

Tel. Journ. Aug 1 1879

Old Broad Street, July 24th, 1879.

ANGLO-AMERICAN TELEGRAPH COMPANY (Limited).—In anticipation of the meeting of this Company the report has been issued. It says: "With £3,587 brought forward, the total receipts of the half-year were £298,393, showing an increase of £25,120 compared with the corresponding period of last year, while the expenses were £54,592. The sum of £75,000 has been added to the renewal fund, and a quarterly dividend of 2 per cent. on the Preferred, and at the rate of 4 per cent. per annum on the ordinary stock has been paid. A second quarterly dividend of 2½ per cent. on the former, and at the rate of 5 per cent. on the latter stock, will be paid on the 1st proximo, leaving £11,300 to be carried forward. In view of the approaching competition of the new French Company, and to facilitate the increased number of messages expected from a lower tariff, it has been determined to lay a new cable next year, for which the shore ends and part of the intermediate types of the 1865 and 1866 cables will be available; while the deep sea section, which will be of the latest improved type, will be paid for out of the renewal fund. The duplex system of telegraphy, invented by Mr. J. B. Stearns, and applied to the cable laid in 1874, has been taken over by the Company as from the 1st March, 1879. The royalty to be paid to Mr. Stearns during the life of his patents, for their use upon the whole of the Company's system, amounts, at present, to £1,300 per annum, the maximum payment being limited to £1,500 per annum. The system will be gradually extended to the whole of the Company's cables."

Iron Aug 1879

UNDERGROUND WIRES IN GERMANY.—A subterranean telegraph wire has just been laid between Hamburgh and Bremen, and Oldenburgh and Emden, with branch lines to Bremerhaven and Wilhelmshaven.

Iron Aug 1 1879

TELEGRAPH RATES TO AUSTRALIA.—It is said that the efforts made by the Royal Commissioners of the Australian Exhibitions to obtain a reduction of telegraphic rates in favour of exhibitors at Melbourne and Sydney have failed of success, solely by reason of the uncompromising opposition of Lord John Manners, who holds "that as the telegrams in question would be sent with the view of facilitating the arrangements of manufacturers and tradesmen who are exhibiting for trade purposes, and because of the pecuniary advantages they are expecting to derive, he can see no reason why the Post-office Department should forego its revenue for their benefit."

LEASE OF THE DOMINION TELEGRAPH COMPANY'S LINES.—It is reported that the lines of the Dominion Telegraph Company of Canada have been leased to an American company on the following terms:—The American Company take up all unissued stock of the Dominion Company ($289,000), at 80 per cent., $140,000, of which is to be applied to pay off floating liabilities, leaving $90,000 to be used in extending the lines, &c. The lessees are to pay for interest on Dominion telegraph bonds $30,000 annually, and at their maturity pay the same off; and pay quarterly in advance 5 per cent. on the capital of $1,000,000, the first quarter's interest being now in hand. They also pay $2500 per annum for the maintenance of the company's organisation, such as board, secretary, &c. The Canadian Board is to be maintained. The lease is for 99 years from the first of July ult., and should the lessees in any way fail to carry out their agreement to pay over quarterly dividends, interest on bonds, &c., the Dominion Company, at the expiration of thirty days, are empowered to terminate the lease.

Telegraphic Journal Aug 1 1879

DIRECT UNITED STATES CABLE COMPANY.—The report of this Company, to be presented at the fourth ordinary general meeting, to be held at the City Terminus Hotel on August 1st, says: "With this report the directors submit the usual statements of account for the half-year ending 30th June, 1879, which, with the half-year's accounts to the 31st December last, presented at the ordinary general meeting on the 21st March last, show the financial result of the second year's working of the Company. For the half-year the revenue, after deducting outpayments, amounted to £87,706 3s. 2d.; for the corresponding period of 1878 the amount of revenue, after similar deductions, was £79,852 11s. 5d. The working and other expenses (exclusive of cost of repairs), interest on loan, and income tax, &c., amounted for the half-year to £20,523 5s. 10d., leaving a balance of £67,182 17s. 4d. as the net profit for the half-year; making, with £5,273 8s. 4d. brought forward from the previous half-years, a total of £72,456 5s. 8d. In the corresponding half-year of 1878 the expenses and payments above mentioned (also exclusive of cost of repairs), amounted to £20,065 17s. 9d. The cost of repairs for the half-year, amounting to £8,965 9s. 11d., has been paid for out of, and is charged against the reserve fund. Three quarterly *interim* dividends of 1¼ per cent. each, amounting to £45,532 10s. 0d., have been declared and paid at the usual times during the financial year, and a final dividend of 5s. per share is now proposed; making, with the three *interim* dividends, 5 per cent. for the year, being a total distribution of £60,710. The appropriation of the above balance of £72,456 5s. 8d. on the revenue account is thus shown:—*Interim* dividend for quarter ending 31st March last, £15,177 10s.; final dividend now proposed, £15,177 10s.; carried to reserve fund, thereby increasing it to £100,000—£34,756 4s. 3d.; written off preliminary and arbitration expenses, £5,000; carried forward to next account, £2,345 1s. 5d.; total, £72,456 5s. 8d. The agreement with the Dominion Telegraph Company of Canada, referred to in the last report, has been completed, and came into operation as from the 1st January, 1879. The break in the Company's main cable, which occurred on the 4th January last, was repaired on the 20th March; and the interruption on the 12th February last, of the short section, was repaired on the 22nd April. Both sections of the cable are in good working order.

Journal of Tel Aug 16 1879

The International Telegraph Conference.

The action of the International Telegraph Conference, as has been before stated, will not be authoritatively known until ratified by the Governments which the delegates represent. Although the English telegraphic journals have made no report of the proceedings or the conclusions arrived at, some of these are made known in speeches of the delegates at the numerous entertainments which are given them.

Journal of Tel. Aug 16 1879

The Telegraphic Journal of August 1st, says:—"The delegates, despite the unseasonable weather, are still diversifying their business with sight-seeing and entertainments. On Saturday, July 12th, they were shown over the West India Docks, by invitation of the East and West India Dock Company. The ships were dressed in their honor, and luncheon was served in one of the large wool warehouses. On Friday, July 18th, the delegates paid a visit to the Camp at Wimbledon, where they were entertained at lunch in the Refreshment Pavilion, by the Joint Reception Committee of the Post Office and Telegraph Companies. And on the following Wednesday they went to Liverpool, and were entertained at a banquet given by the Lord Mayor, and a luncheon on board one of the Inman steamers. From Liverpool they then proceeded to Edinburgh and Glasgow."

At Edinburgh the members were entertained by the Lord Provost, Magistrates and Town Council to a cake and wine banquet in the Council Chambers. The Lord Provost presided, and a large and brilliant assembly were invited to meet the delegates.

Mr. C. H. B. Patey, Assistant Secretary, General Post Office, London, a member of the Conference in proposing the toast of "The Edinburgh Chamber of Commerce" said, speaking of the work of the Conference, "In regard to the tariff with Europe, that also would be found to be lowered in some instances very considerably, more especially to the four countries with which England had its greatest intercourse—France, Belgium, Holland, and Germany. In regard to these there would be a decrease, but that was not to be wondered at when he told them that of the messages to foreign countries 80 per cent were to those he had named. In connection with the word code a change was brought about by the Conference at St. Petersburg, which preceded that of London. The only difference now was that in the number of languages allowed for code messages the Turkish had been excised, leaving eight languages."

At the banquet given to the delegates at Manchester by the President of the Manchester Chamber of Commerce, Mr. Patey proposed "The Manchester Chamber of Commerce," and gave an account of the labors of the Conference. He said they had come to the conclusion that a word rate should be introduced, and he hoped that in the course of the next year or two that rate would be in operation for the European telegraphs. The differential rate between London and the country would be done away with, and next year there would be only one rate to any part of the United Kingdom or the world. He thought they had been able to hit upon a tariff which would continue to pay dividends, and still give satisfaction to the public. It would be found that a great reduction had been made in all the rates. With regard to European code messages scarcely any alteration had been made. Another alteration had been made which he also thought would be for the benefit of the merchants. Heretofore they had been permitted to send five figures as one word, and some difficulties had arisen in connection with this. The Conference had decided that the extra payment for figure telegrams should be altogether abolished, but that, on the other hand, the number of figures allowed to count as one word should be reduced to three.

Telegraphic Journal Aug 1 1879

Notes.

Tel. Journ. Aug 1 1879

THE INTERNATIONAL TELEGRAPH DELEGATES.—The delegates despite the unseasonable weather, are still diversifying their business with sight-seeing and entertainments. On Saturday, July 12th, they were shewn over the West India Docks, by invitation of the East and West India Dock Company. The ships were dressed in their honour, and luncheon was served in one of the large wool warehouses. On Friday, July 18th, the delegates paid a visit to the Camp at Wimbledon, where they were entertained at lunch in the Refreshment Pavilion, by the Joint Reception Committee of the Post Office and Telegraph Companies. And on the following Wednesday, they went to Liverpool, and were entertained at a banquet given by the Lord Mayor, and a luncheon on board one of the Inman steamers. From Liverpool they then proceeded to Edinburgh and Glasgow.

Engineer July 25 1879

SOCIETY OF ENGINEERS.—Arrangements have been made for a visit of the members and associates of the society, on Wednesday, the 30th instant, to the telegraph cable works of Messrs. Siemens Brothers, at Charlton, by their kind permission. The visitors will there have the opportunity of inspecting the various processes connected with the preparation of the materials used in the manufacture of telegraph cables, and the manufacture of the cables themselves as well as that of various kinds of electric telegraph apparatus and instruments. The telegraph cable ship Faraday will also be open for inspection, through the kindness of Messrs. Siemens Brothers. Members and associates, who are requested to state their intention to attend, will assemble at Messrs. Siemens's Works at 11.45 o'clock. A convenient train leaves the Charing-cross Station at 11.0, and the Cannon-street Station at 11.10, for the Woolwich Dockyard Station. Arrangements will be made for those members and associates who wish to do so, to dine together, at the Guildhall Tavern, Gresham-street, at 6 o'clock.

Engineer July 25 1879

96 Telegraphic Journal Aug 1 1879

THE EASTERN TELEGRAPH COMPANY (LIMITED).—At the fourteenth ordinary general meeting of this company, held on July 14th, the chairman, having moved the adoption of the report, an abstract of which appeared in our last issue, and the same having been seconded by the Marquis of Tweeddale, said in answer to questions by shareholders: Is there any other question to be put? Well, then, I may say to Mr. Newton, in the first place, that I think we have shown you that there is an increase in the stations alone of 12 stations, and I think that the gross increase that we shew you is £6,000 odd. Then there is —— Mr. Newton: £6,160 in the half year; that means £12,320 per annum. The Chairman: Yes; quite true. Well, if you take 12 stations, and take them at an average of £500, you have £6,000 to begin with, and if you take the loss of £7,000 on exchange you have the net amount without any difficulty. As to fluctuations in the exchange it is very difficult for me to give an opinion. The wisest men at the present moment are baffled by this question of silver, and if there is any hon. gentleman who can throw any light on the subject I am sure that it will not only be acceptable to me and the Board generally, but also acceptable to a great many others who are deeply interested in the trade; but I may mention to you that we have not been idle and have not been thoughtless on this particular question, and we have entered into an arrangement now with the Indian Government which will give more favourable terms to the company as regards the value of the rupee. Mr. Newton: That leads me to another question. Have you some arrangement with the Government that they take any risk of the fluctuations in the price of silver and in the value of the rupee? As I understand it you collect your revenue in Calcutta in rupees. We cannot take any benefit from the Government in that respect; we must take the chance if the exchange is 1s. 6d. And I do not think that we ought to consider that we make a loss on exchange unless you, for convenience in the accounts, take the value, say at 20d., which is 1s. 8d. in our money, but received abroad in the rupee. We certainly must take the risk of it being remitted home, like any merchant, unless the Government is so kind as to give us an increase on the value to that prevailing in the markets abroad. That is what I mean—not that we take any benefit from anyone, but that we take our chance like any merchant. The Chairman: I think that if you asked any merchant who sends out goods to Calcutta he will tell you that it is a question of the exchanges where he makes a loss where otherwise he expected a profit. But the Indian Government forms part of our joint purse; and in future we have arranged with the Government that it is to be taken at about 1s. 7½d., and, therefore, any variation below that must be to our detriment; but above it, as it is now, it is in our favour. Now, gentlemen, I think those are the only two questions I have been asked, and I hope that I have answered them satisfactorily. The resolution for the adoption of the report was then put to the meeting and carried unanimously. The question of the Cape cable was then discussed at considerable length, Mr. Newton remarking on the want of a limit to the increase of preference and debenture capital when compared with the ordinary capital of the Company. He also said, "Seeing the tremendous influence of our directors, I am amazed that, as to that part of which so much is made, the influence of the directors with the Government has not produced us a better bargain; and it would seem that the influence is not worth so much, seeing the results of this new undertaking; and the sooner you get on your board two or three more gentlemen of consummate mercantile capacity (hear, hear), the better will it be not only for you, sir, and your Company, but for every member of telegraph property." The chairman then proposed the following resolution:—"Resolved, that the several provisional agreements referred to in the directors' report, and submitted to this meeting with the Lords Commissioners of Her Majesty's Treasury, the Colonial Governments of the Cape of Good Hope and Natal, the Portuguese Government, and the Sultan of Zanzibar, with respect to a line of submarine telegraph between this Company's station at Aden and Natal, and the arrangements mentioned in the report as to the making, laying, and working of the cables, be and the same are hereby approved and adopted so far as the same relate to the matters and things to be done by this Company, and that the board of directors be and they are hereby authorised on behalf of this Company to complete and carry into effect the said agreements and arrangements, with or without any modifications or alterations from time to time required or approved by the board; and also to make and carry into effect any other agreements and arrangements with reference to the said cables which the board may think desirable; and also to subscribe for and accept on behalf of the Company shares and debentures of the proposed Eastern and South African Telegraph Company; and to raise, by the issue of debentures of this Company or otherwise, such moneys as may be required for those purposes or any of them, and apply the same accordingly as the board shall from time to time deem expedient." Sir James Anderson seconded it, and, after some further critical remarks by Mr. Newton, it was put to the meeting, and carried with one dissentient. The usual vote of thanks then brought the proceedings to a close.

The Eastern Extension Telegraph Company (Limited) notify that the Six per Cent. Debentures, due on August 1st, will be paid on or after that date, on presentation at the Consolidated Bank.

The Eastern Extension Telegraph Company (Limited) notify that their Java-Darwin cable is now repaired, thus restoring direct telegraphic communication with Australia and New Zealand.

The *Faraday*, steam screw cable ship, has returned to Messrs. Siemens Brothers' Telegraph Works, Charlton, after having successfully laid 200 miles of the shore end of the new French Atlantic cable in course of being laid down from St. Pierre to the United States. The *Faraday* will shortly begin to take on board the first portion (about 1,000 miles) of the deep sea cable, and is expected to make three voyages before France and America are placed in direct and independent communication.

The following are the final quotations of telegraphs:—Anglo-American, Limited, 53½-53¾; Ditto, Preferred, 82½-82¾; Ditto, Deferred, 26½-26¾; Brazilian Submarine, Limited, 6½-7½; Cuba, Limited, 7¾-8¼; Cuba, Limited, 10 per cent. Preference, 15¾-16¼; Direct Spanish, Limited, 1¾-2¼; Direct Spanish, 10 per cent. Preference, 10¾-11¼; Direct United States Cable, Limited, 1877, 10¼-10¾; Eastern, Limited, 7¼-7¾; Eastern, 6 per cent. Debentures repayable October, 1883, 105-108; Eastern 5 per cent. Debentures repayable August, 1878, 103-106; Eastern, 6 per cent. Preference, 11¾-12; Eastern Extension, Australasian and China, Limited, 7¾-8; Eastern Extension, 6 per cent. Debenture, repayable February, 1891, 108-111; German Union Telegraph and Trust, 7½-8; Globe Telegraph and Trust, Limited, 4½-5½; Globe, 6 per cent. Preference, 10½-11¼; Great Northern, 8½-8¾; Indo-European, Limited, 20½-21½; Mediterranean Extension, Limited, 2½-3; Mediterranean Extension, 8 per cent. Preference, 9-9½; Reuter's, Limited, 9-10; Submarine, 229-234; Submarine Scrip, 2-2½; West Coast of America, Limited, 1-1½; West India and Panama, Limited, 1½-1¾; Ditto, 6 per cent. First Preference, 7½-8½; Ditto, ditto, Second Preference, 7¼-7½; Western and Brazilian, Limited, 2¾-3¼; Ditto, 6 per cent. Debentures "A," 96-100, Ditto, ditto, ditto, "B," 89-94; Western Union of U.S. 7 per cent., 1 Mortgage (Building) Bonds, 118-122; Ditto, 6 per cent. Sterling Bonds, 107-109; Telegraph Construction and Maintenance, Limited, 30-30½; Ditto, 6 per cent. Bonds, 106-108; Ditto, Second Bonus Trust Certificates, 2½-2¾; India Rubber Co., 12¾-13¼; Ditto, 6 per cent. Debenture, 106-109.

Journal of Tel Aug 1 1879

The Telegraph.

ANGLO-AMERICAN TELEGRAPH.

THE report states that the total receipts for the past half-year, including a balance of £1,687 brought over from the last account, amount to £298,293, being an increase of £25,120 as compared with the corresponding period last year. The total expenses amount to £51,692. Out of this sum the directors set apart £75,000 to the renewal fund, leaving a balance of £168,800. One quarterly interim dividend, of 2 per cent. on the preferred stock, and at the rate of 4 per cent. per annum on the ordinary stock, was paid on May 1, 1879, absorbing £70,000, leaving a balance of £98,800, from which a second quarterly dividend of 2½ per cent. on the preferred stock, and at the rate of 5 per cent. per annum on the ordinary stock, will be paid on August 1, 1879; leaving a balance of £11,300 to be carried forward to next account. The 1869 cable, laid down by the French Atlantic Telegraph Company between Brest and St. Pierre, and taken over by this company in 1873, was broken on February 22 last. The necessary repairs are now being proceeded with. The short section of the same cable, laid between St. Pierre and Duxbury, has been broken twice during the half-year; both breakages have been repaired, not without considerable difficulty and delay. The *Minia* has been engaged in the restoration of the main and short sections of the cables belonging to the Direct United States Cable Company. The policy to be pursued, in view of the approaching competition with the new French company, "La Compagnie Française du Télégraphe de Paris à New York," of which M. Pouyer Quertier is the president, is occupying the constant attention of the directors; and it has been determined that, in order to preserve for the Anglo-American Company the position and prestige they have hitherto enjoyed, and to facilitate the transmission of the increased number of messages which may be expected from a lower tariff, a new cable should be laid by this company next year. The shore ends, and a considerable portion of the intermediate types of the 1865 and 1866 cables, will be available for this purpose; the deep sea section will consist of new cable of the latest improved type, and will be paid for out of the renewal fund. The duplex system of telegraphy, invented by Mr. J. B. Stearns, and applied to the cable laid in 1874, has been taken over by the company as from March 1, 1879, and will be gradually extended to the whole of the company's cables. It is proposed to establish a fund for the benefit of the officers of the company, to which the company will subscribe half the annual premiums. This fund will, to a great extent, stand in place of a periodical augmentation in the salaries of the staff, and will, besides, make the service more popular.

Iron July 26 1879

THE DIRECT UNITED STATES CABLE COMPANY.

THE report of the Direct United States Cable Company (Limited), for the six months ending 30th June last, states that the revenue for the half year, after deducting out-payments, amounted to £87,706; the amount of revenue for the corresponding period of last year, after making similar deductions, being £79,852. The working and other expenses (exclusive of cost of repairs), interest on loan, and income tax, &c., amounted for the half year to £20,523 5s. 10d., leaving a balance of 67,182 17s. 4d. as the net profit for the half-year, making, with £5273 8s. 4d. brought forward from the previous half-year, a total of £72,456 5s. 8d. In the corresponding half-year of 1878 the expenses and payments above mentioned (also exclusive of cost of repairs) amounted to £20,065 17s. 9d. The cost of repairs for the half-year, amounting to £8965 9s. 11d., has been paid for out of, and is charged against, the reserved fund. Three quarterly interim dividends of 1¼ per cent. each, amounting to £45,532 10s., have been declared and paid at the usual times during the financial year, and a final dividend of 5s. per share is now proposed, making, with the three interim dividends, 5 per cent. for the year, being a total distribution of £60,710. The appropriation of the above balance of £72,456 5s. 8d. on the revenue account is thus shown:—Interim dividend for quarter ending 31st March last, £15,177 10s.; final dividend now proposed, £15,177 10s.; carried to reserve fund, thereby increasing it to £100,000, £34,756 4s. 3d.; written off preliminary and arbitration expenses, £5000: carried forward to next account, £2345 1s. 5d.

NEW SUBMARINE CABLES.

AFTER a period of stagnation extending over five years, there is again a revival of submarine cable enterprise; and cable electricians, who have been for that time deprived of their legitimate occupation, are now experiencing brighter prospects. There are no less than four distinct cables in course of being manufactured or laid; and others are projected. Last year the Eastern Telegraph Company completed the duplication of their Oriental lines from England to Bombay; and the Eastern Extension Telegraph Company, which prolongs the Eastern Company's system to Australia *viâ* Madras, Penang on the Malay Peninsula, and the East Indian Islands, are at present engaged in duplicating their lines also, a work which has been somewhat delayed, however, by their giving up 1400 miles of ready-made cable to form a portion of the cable to the Cape. The latter important line of communication is, of course, the chief cable operation now in hand, and we regret to see that there was some delay in the furtherance of the work, for the s.s. Kangaroo, belonging to the Telegraph Construction and Maintenance Company, who are the contractors, although she arrived at Durban on May 21 with the Natal to Zanzibar section on board, had not begun to lay her cargo up till June 17. For some unaccountable reason a valuable month was lost by this cable steamer, although the need for the cable is, or at least was, so urgent. It is to be hoped that the difficulties in the way, whether due to bad weather, or faults in the core, or to the rumoured refusal of a subsidy by the colony of Natal, on the ground that the terminus ought to be within the Natal borders, have by this time been smoothed away, and that the line is now laid as far as Zanzibar. The second section is on its way out in the s.s. Seine, and the s.s. Calabria carried the remainder.

The agreement between the Eastern Telegraph Company and the Government requires that the entire cable shall be capable of transmitting fourteen words a minute, and that the company shall, save in case of *force majeure*, have the portion of the cable between Durban and Zanzibar opened for traffic by July 31, and the entire line by the last day of this year. The company agrees to keep a repairing ship properly equipped in the Red Sea or Indian Ocean for maintaining the line. All Government messages, whether imperial or colonial, are to have priority to all other traffic, at one-half the rate charged to the general public. The public rate is not to exceed 5s. per word between Durban and Aden; 4s. per word between Zanzibar and Aden; and between Aden and London, by the Eastern Telegraph Company's lines, the sum of 3s. 9d. per word. The total charge for a message from Durban to London must not, therefore, exceed 12s. 9d. per word. Her Majesty's Treasury may nominate an official director on the boards of the companies owning and working the line, to whom every information must at all times be afforded. On the completion of the line between Natal and Zanzibar, the Treasury agrees to pay, during a term of 20 years, an annual subsidy of 17,500*l*., and a like sum on completion of the line between Zanzibar and Aden, provided always that the line is kept in good working order. In case of war, rebellion, or other emergency, the Imperial Government or the Government of any British colony or possession duly authorised by her Majesty's Government so to do, may take possession of the cables, stations, offices, and apparatus on the line, and keep possession of them for as long as they may think fit. For this privilege the Government agrees to make a reasonable compensation to the company. The last clause provides that the agreement shall not be binding until it has been approved by a vote of the House of Commons. It is, we think, a wise foresight on the part of the Government to arrange for taking possession of the lines themselves if need be; and the day is perhaps not far distant when not only the Cape cable, but also the Indian cables of the Eastern Telegraph Company, may become the property of the nation.

The second great cable enterprise now in progress is the Pouyer-Quertier scheme for two Atlantic cables from Brest to New York. This project was ostensibly put forth as designed to gratify the *amour propre* of the French people, who wished to have Atlantic cables of their own. But the offer of the Anglo-American Company to sell or lease them a cable was declined, and the original plan adhered to. It is probable that the ultimate aim of the new company is to compete with the existing Atlantic cables for English as well as Continental traffic, a supposition which is borne out by the fact that the Scilly Islands off the coast of Cornwall have been chosen as an intermediate landing-point for the cable. The new cables are being made by Messrs. Siemens Brothers at their Charlton works, and the s.s. Faraday, which laid the direct United States cable, has already submerged the Brest to Scilly section of the first line.

Within the limits of Europe itself a short cable made by Mr. Henley for the Russian Government was recently laid across the Caspian Sea; and there is now in process of manufacture a new German-Norwegian cable intended to connect Scandinavia direct with Germany. Hitherto the latter power has been obliged to send all her telegrams to Norway through Denmark and Sweden, a course which was irksome to her owing to the uneasy political relations which have for a long time existed between her and Denmark. The agreement entered into between the representatives of the German Empire and the Governments of Norway and Sweden stipulates that Germany shall lay the new cable at her own cost. It is to be a three-wired line and will be laid from Romoe, an island off the west coast of Schleswig, and the Norwegian peninsula, at a point near Arendal. At the latter place it will be connected to the whole Scandinavian telegraph system. The cable is estimated to cost 95,000*l*. and will belong to Germany, who will also repair it. All telegrams from Norway to Germany are to pass through the new line, and also three-fifths of the Norwegian traffic with other countries (excepting Russia, England, and Denmark), unless the new route should prove more expensive than the old ones. It is obvious that this arrangement will materially reduce the inland telegraph revenue of Denmark, for hitherto all the German-Norwegian traffic has passed through that country. The new cable is, we believe, being manufactured by Messrs. Siemens and Halske, of Berlin, and it is expected to be laid some time in August.

Besides these actual performances, there are at least two projects for new submarine cables afloat; one by the American Cable Company to lay a line from New York to Flores, an island of the Azores, with one connecting line from Flores to France, England, and Holland, and another from Flores to Fayal (Azores), Sao Miguel, and Lisbon. These will comprise 7300 miles of line, if they are ever executed. The other scheme is for the long-talked-of Pacific Ocean cable from some point on the western coast of the United States to the Sandwich Islands, and thence to Japan and China. Mr. Cyrus W. Field, the cable veteran of Atlantic fame, is the chief promoter of this undertaking, and he is now in England for the purpose of investigating the subject of making and laying the cable in question. He holds, it appears, an exclusive concession from the Government of the Sandwich Islands for such a cable; a fact which was first announced at the recent Cable Jubilee or celebration of the twenty-fifth anniversary of the organisation of the first Atlantic Cable Company. Similar concessions have yet to be obtained from China and Japan, but as the Celestials are now awake to the advantages of the telegraph, it is expected that these will be obtained without difficulty. On the return of Mr. Field to America a company will be formed to carry out this work, and Mr. Field has, we understand, agreed to contribute 100,000 dols. as a subscription to the capital stock. The establishment of this cable would complete the telegraphic circuit of the world, and we can only hope that Mr. Field will be as successful in carrying the electric wire across the Pacific Ocean as he was in spanning the Atlantic.

ELECTRICITY & TELEGRAPHY

Aug 2 1879

INTERNATIONAL TELEGRAMS.

THE *Daily News* takes a discouraging, but not wholly incorrect, view of the work done in London by the recent International Conference. A general demand for cheap telegraphy, it says, has been met, not by a general reduction of tariffs, but by concessions as to the form of messages; and the word-tariff has, with certain modifications, been adopted for general use. The old idea of a minimum message has been given up, and what may be called a fixed or constant charge made instead; and the method of charging for long messages has naturally undergone alteration. It will be recollected that, under the system now existing, a minimum message, including name and address, is fixed at twenty words, which must be paid for whether as many words be required or not; and that the charge increases by so much per ten words. Thus, if a message be, including names and address, only five words, twenty must be paid for, while if it require twenty-one words thirty will be charged, as the rate of increase is at so much per ten words. The system of a high initial charge has been throughout defended by the argument that a message is a message, whether it be short or long, and that the same prefixes and terminal charges are required for both. It has, however, been found possible to combine a fixed initial charge with a simple word-tariff in such wise as to relieve the senders of short messages of considerable expense. It is understood that the submarine companies expect to sustain a certain loss by this modification, which, so far as short mercantile telegrams are concerned, amounts to nothing less than a reduced rate of charges, but hope to recoup themselves by a large expansion of this part of their business.

The solution of the difficulties between the advocates of a simple word tariff and those who cling to a minimum message of such length as to prove remunerative to the lines has been found in a first charge at the rate of five words for a telegram, and after that at so much per word according to the existing tariff. To make this clear in intention, it may be mentioned that the telegraph companies consider the "prefixes"—that is, the preliminary messages exchanged between the clerks before the actual message is dealt with—equivalent, with the trouble of collection and delivery, to five words. In practice, it makes it possible to send a short message at a very low rate. To take the example of a telegram from England to Italy. To begin with, the shilling extra from English places other than London is abolished, leaving the minimum telegram of twenty words. For this the charge is now seven shillings and sixpence, with increase by ten words at the rate of fourpence per word. Taking this rate as the basis of calculation, the new telegram would be computed thus. An initial charge of five words, one shilling and eightpence; message of, say, eight words, 2s. 8d.—In all 4s. 4d. This is a very great reduction. But it may be objected that a message of eight words is a very short one. It is in fact much longer than it appears at first sight. To persons accustomed to correspond by telegraph the address only consists of three words—for instance, Brown to Black, of Rome. Brown does not need to send his address, and the full name and address of Black at Rome are kept in a private directory at the telegraphic office—a privilege costing him about a guinea per year. He has, therefore, five words left free—often more than enough, inasmuch as Brown to Black, at Rome, "Yes," would often be sufficient, and would be charged as only four words in addition to the initial five; making a message of simple assent cost no more than 3s. This, then, is the effect of the new scale of charges on inter-European telegrams. It is hardly necessary to state that the simple word-tariff without initial charge has been in use since the Convention of St. Petersburg on extra-European lines.

The regulations laid down by the Conference of London as to the definition of a word are minute to the extreme, and would appear amusing if the artful devices of "packers" were not well known. Great ingenuity has been expended upon the concoction of words conveying the meaning of a sentence, and a species of duel has been going on for some time past between the "packers" and the companies—the latter protesting against the use of "words of learned length and thundering sound," obviously intended to defraud them of what they consider their lawful dues. Code-makers have carried the art of building up sentence-words to such a pitch at last that the companies have turned upon them and obtained from the London Conference a definition of what a word, telegraphically speaking, is. For inter-European purposes a word may contain fifteen characters according to the Morse alphabet, but beyond Europe ten characters only. Thus, "responsibility" is one word for European, but two for extra-European telegraphy.

By the abolition of the signature previously required, a concession has been made which almost compensates for the insistance on a telegram being properly directed. This latter provision, however, is not very exacting. Two words only are actually obligatory, and these must be the name and address of the person to whom the telegram is sent. It is, perhaps, well that the name, signature, and address of the sender should not be required. Many bickerings have arisen over the question of signature, and probably would have occurred again, had it not been determined not to ask for it at all. Still the telegraph officers retain the right of compelling the sender of a telegram to establish his identity whenever they think fit. The remainder of the work of the International Telegraph Conference has been in the direction of minute but necessary regulations for the adjustment of the order in which messages shall be sent, and other arrangements for the more perfect management of international telegraphy. Government telegrams take precedence of all others, and are followed in the order of transmission by service telegrams and the "urgent" private telegrams, for which a triple rate is charged in the countries—all except India and England—in which "urgency" is recognised. These "urgent" private telegrams, which take precedence of ordinary messages, appear to pass mainly between operators on the various Continental money markets, to whom the cost of a message is probably of slight importance.

The effect of the Conference of London will unquestionably be the destruction of any hope of cheap and popular international telegraphy being introduced for some little time—at least till after the Conference to be held in Berlin in 1884. The concessions made in form and price are all, it will be observed, to regular customers, merchants, and others whose "code," name and address are kept at the terminal office. Senders of telegrams who are compelled to write name and address of sender and destinee at full length will profit but very little, if at all, by the revised code of 1879, which may be regarded rather as a politic concession than the initiation of a new system. It must, however, in fairness be recognised that the great submarine lines are commercial speculations working for a profit, and therefore hardly to be discussed on the same principle as land telegraphs, managed by the Governments of the countries through which they pass. The latter may be regarded by any Government so disposed as part of the machinery of national life, and not therefore compelled to return a profit; but so long as the ocean lines remain in private hands, these theories are obviously inapplicable to them. Merchants, however, have cause to thank the delegates to the London Conference for relieving them of most of the ignominious necessity and opportunity for getting the better of the telegraph companies. It may be added that the amendments of the Conference have yet to receive the formal ratification of the several Governments concerned, and that they are not intended to take effect before April, 1880.

100

THE NEW CAPE CABLE.

from July 26/876

THE works of the Telegraph Construction and Maintenance Company, on the riverside just below Greenwich, present just now rather a decided contrast to a great many factories and business places down the river below London Bridge. Very unmistakeable are the symptoms of dulness and stagnation that are here everywhere visible—warehouses and wharves to let, workshops closed, and one fancies a good deal less than the average of shipping in the river, the general depression in appearance being very much enhanced by the unfortunate ferry between Rotherhithe and Wapping, which, after a chequered career, appears to have finally broken down, and now lies a conspicuous and particularly dreary representative of the hard times. It is an ill wind, however, that blows nobody any good, and the mischievous breezes that have blown up for us the expense and anxiety of a vexatious war in South Africa have wafted to the Telegraph Construction Company a good substantial contract for a new line to bring our distant and troublesome possessions at the Cape into ready communication with us. The line is now in rapid construction, and this, together with another submarine cable for connecting Germany with Norway, a duplicate line from Penang to Australia, and one or two others, keeps the wheels spinning merrily at the Company's works; which are just now, therefore, particularly well worth visiting, more especially as the manufacture is of a kind at once pretty and simple enough to be readily comprehended by any one unfamiliar with such operations.

The actual conducting wire, which, of course, is really the telegraphic line, is not made at the works now under consideration, but is imported from the company's establishment just off the City Road, where the heart of the whole cable is formed by encasing a seven-strand copper wire in a coating of gutta-percha. When completed it is wound on huge reels, in lengths of about three miles, the copper conductor and its insulating covering being somewhere about the thickness of a lead pencil, the copper and gutta-percha bearing, in point of bulk, about the same relation to each other as the "lead" and the cedar. On their arrival at Greenwich from the City Road the reels are immediately plunged into circular tanks of water, from which, as they are required, they are drawn by a crane and deposited in a trolly running upon a tramway laid throughout the length of the large machine-room in which operations are commenced. Each reel is rolled from the trolly on to the floor, lifted by means of screws placed under the ends of its axle, and the line may now be spun off as rapidly as desired. The whole process from this starting point until it is coiled on board the vessels that are to pay it out into the ocean is a process of protection and strengthening. It is first incased in a covering of cotton tape by a method which will be familiar enough to anybody who has seen ropemaking, a reel of the tape being made rapidly to revolve round the insulated wire as it is paid out. This is the manner in which every succeeding layer is applied and it may serve to render it more intelligible to any one who does not happen to have seen rope, making if we say that the process may be very fairly illustrated by drawing a wire slowly through the axle of a wheel with a reel of cotton fixed on one of the spokes. The reel, of course, will revolve round and round the centre, and if the end of the cotton be attached to the wire it will be gradually unwound from the reel and twisted spirally round the wire as it passes along.

The early deep-sea cables suffered terribly from the ravages of a minute marine insect, which ate its way through the insulating materials. To guard against this enemy the next covering—applied in precisely the same way, only that the winding is done in a direction opposite to that in which the cotton tape is twisted—is a brass tape which covers it so completely that the insects can find no way to the materials within. Next comes a similar sheathing saturated with marine glue—this, again, being twisted round in the direction contrary to that of the brass. Several reels of jute yarn are now spun round the whole, thus completing the case of the cable. The rapidity and beautiful simplicity of the whole of the work may be gathered from the fact that all this is done while the line is merely passing from one side of the room to the other. On this side the room is the reel of insulated wire, just as it comes into the factory; on the other are the "core tanks," in which is coiled the telegraphic line perfectly complete and capable of conveying messages and resisting all the ravages of marine animal life, and the effects of prolonged immersion at great depths of sea water, only that it requires to be strengthened.

From this point the proceedings vary somewhat according to the position for which the line is intended. The shore ends, which are to be exposed to the action of tempests and jagged rocks, are encased in solid thick galvanised wires, which bring up the weight of the completed cable to some 10 tons a mile. The deep sea cable is wound round with a slighter wire of homogeneous iron, which is first heated in a furnace to expel any air that it may contain, and then plunged into cauldrons of a boiling black varnish, calculated to effectually exclude the action of the water. The winding of these homogeneous wires, and the similar proceeding with the stouter wires for the shore ends, is in principle precisely the same as in the operations already described, but of course on a much more gigantic scale, and presents one very pretty feature. The core around which the strengthening wires are to be wound passes up through the room, coming in by a hole in the floor, and passes out by a hole in the ceiling directly over. As it moves up, a considerable number of reels of wire of any required kind or thickness revolve round it like the horses in a "merry-go-round," or like children round a may-pole, with their ribbons attached to the top of the pole. Just according to the speed with which the "core" is drawn up through the ceiling, their revolutions around it are performed, and the wire they pay out is wound round with a regularity and compactness simply perfect. The very pretty feature alluded to is a mechanical arrangement known in the engineering world as the "sun and planet" system, which keeps the reels always with the same side presented to the line around which they are so merrily spinning. The floor on which a number of these urchins are at work is a particularly lively one, inevitably suggesting the idea of a number of "merry-go-rounds" at a fair, an idea which is further sustained by the clanging of bells with which each machine is provided to stop or start. On the floor above, the apex of each maypole, so to speak, is seen protruding through the floor. The core as it passes off from this apex is found to be sheathed in iron, and very little remains to be done with it. First, another tape is wound round, and then a stream of what looks like tar is copiously poured upon it; then another tape and another stream and finally it passes out of the building through two sets of wheels, one running against another, and grooved so as to exactly fit the cable as it passes between them. Two of them run horizontally and two perpendicularly. Thus the whole is well squeezed in a perfectly circular form. Tanks as big as small houses, and capable of holding 200 miles of deep-sea cable, are ready to receive it as the completed line squeezes its way between these wheels. As it passes through, a couple of men coil it down in regular layers, each layer being whitewashed over, to prevent sticking together, and the whole receptacle being filled up ultimately with water, until the vessel is ready to receive it into similar tanks on board.

Of course it has to be tested, and for this purpose each section of cable is put in communication with the sanctum of the electrician. Every now and again a current is passed through it, and observation made of its effect on a tiny magnet. The way this is done is very curious. The magnet has a little mirror at its back, and this mirror is made to reflect a ray of light on a graduated scale. The most trivial movement of the magnet is thus shown, and the position of the little slit of light on the scale tells at a glance whether all is right. About 50 miles a day is the rate at which this, we believe the largest manufactory of the kind in the world, can turn out completed cable, and it is expected that by the end of the year the line completing our communication with the Cape will be laid. A portion of cable originally intended for the duplicate Australian line has been appropriated to this more urgent contract, and already three out of the four sections have been despatched. From Natal to Delagoa, a distance of about 350 knots, thence to Mozambique, a distance of 1000 knots, and from there on to Zanzibar, some 650 knots, are the sections already completed; and the remaining 2000 knots required to connect Zanzibar with Aden are being rapidly proceeded with.

101

mauvais temps impriment au navire de forts mouvements de tangage et forcent le frein à laisser dérouler par soubresauts, selon que le navire monte sur la lame ou descent avec elle.

Les efforts sous lesquels ces ruptures ont lieu, sont de 7,800 kilog. au maximum; mais sans atteindre à une pareille traction, on peut craindre tout au moins des avaries notables.

Ce sont là probablement les causes déterminantes de la variation de la durée des cables; car il y en a qui ont besoin de réparation au bout de très peu de temps, d'autres au contraire n'en ont subi aucune depuis leur pose

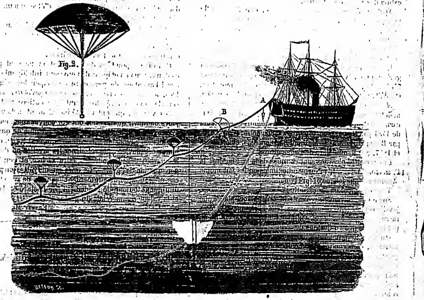

Fig. 2.

Fig. 103.

qui date de près de vingt ans; cela tient évidemment aux conditions dans lesquelles ils ont été immergés.

Le premier cable posé a cessé de fonctionner au bout de vingt-quatre jours.

Si on laisse le câble se dérouler naturellement, son poids l'oblige à descendre suivant une ligne D presque verticale (fig. 1), et il est certain que cette position le fatiguera beaucoup plus sérieusement que la ligne ABC; or, c'est pour parer à cette fatigue démesurément augmentée dans les mauvais temps, que M. Dronlor, un ingénieux industriel scientifique, a eu l'idée d'appliquer à l'immersion des câbles un parachute, offrant absolument la forme d'un parapluie (fig. 2), dont l'axe est une corde terminée par une boule de plomb.

Au commandement, un homme tenant d'une main le parachute, de l'autre lancerait la corde munie de plomb, par un mouvement qui peut être comparé au coup de fronde, de manière à ce que la corde s'enroulant autour du câble puisse l'amarrer solidement. Le parachute occuperait successivement les positions A, B, C, et par sa résistance dans l'eau obligerait le câble à descendre doucement et sans danger pour lui.

Si l'on suppose la vitesse de descente du 2 mètres par seconde, le poids soutenu par le parachute serait de 600 kilos environ; supposons que 1,000 mètres de câble pèsent 370 kilos, on voit qu'avec un parachute par kilomètre, le câble ne descendrait pas dans les profondeurs de la mer avec une vitesse de plus de 2 mètres par seconde; mais en tenant compte de la traction opérée par la rapidité du navire, on peut dire que la descente se ferait alors suivant une ligne se rapprochant de l'horizontalité, qui non-seulement atténuerait beaucoup les effets de tangage, mais encore soulagerait presque complètement le frein dans le poids qu'il a à supporter.

Si nous passons maintenant de la théorie à la pratique, nous trouverons que le prix d'un parachute en toile à voile, d'un mètre superficiel, peut revenir à 3 francs.

Nous avons parlé ci-dessus d'un parachute par kilomètre, pour obtenir une descente de 2 mètres par seconde; mais, par les temps très calmes, il pourra se faire que l'on n'ait pas besoin d'avoir recours au parachute, ou bien qu'on n'en utilise qu'un par 2 kilomètres. Pour ne pas avoir de mécomptes, supposons que l'on ait à en employer un par kilomètre. Si le câble a 3,500 kilomètres, comme celui dont l'immersion est à l'étude, il suffirait donc de 3,500 parachutes, soit une dépense de 10,500 francs,

over

somme bien peu considérable si l'on tient compte du capital consacré à l'entreprise. Selon toute probabilité, cette dépense se changerait en une grosse économie immédiate, sans parler des garanties qu'elle donnerait pour sa durée.

Le transport des parachutes à bord ne peut être une question ; pliés, jusqu'au moment de leur emploi, ils n'occuperont qu'un emplacement des plus restreints.

Il n'y a aucuns frais accessoires à faire ; M. Dronier n'a pas pris de brevet et abandonne à tous son idée et le résultat de ses travaux.

Ce projet, du reste, n'est pas nouveau ; *les Mondes* en ont dit quelques mots en 1865. Depuis cette époque, aucune objection, aucune critique ne sont venues affaiblir la confiance de l'auteur du projet dans la facilité et l'efficacité de son application.

Nous avons cru devoir appeler de nouveau l'attention sur cette question, parce que l'idée nous paraît simple, pratique et toute d'actualité.

THE SUBMARINE TELEGRAPH COMPANY LIMITED.—Since writing the above notes, the half-yearly ordinary meeting of this Company has been held, Sir James Carmichael presiding. The report of the directors for the half-year ending 30th June last recommended a dividend at the rate of 17½ per cent. per annum, and to add the usual proportion of the receipts to the reserve fund. It also stated the directors had established, in concert with the German Union Telegraph Company, a duplex system of telegraphy on a wire between London and Emden for the transmission of messages passing over the special wire erected by the company between Emden and Vienna.—The Chairman, in moving the adoption of the report, congratulated the shareholders on the balance sheet, which, while showing a slight increase in traffic, did not show a corresponding increase in the expenditure. With regard to the alteration of tariff contemplated, the shareholders were aware that the directors had from the commencement of the company always been advocates of moderate rates. Many years ago, he (the Chairman) endeavoured to obtain a reduction of the present rates from the French Government, and an assimilation of the differential rates from Liverpool, Glasgow, &c., to the Continent. The French Administration did not see their way to meet the wishes of the company. At a late telegraph conference in London there was an almost general expression of opinion in favour of a word tariff. Personally speaking, he would have preferred taking a more medium course, commencing with a ten-word rate. This was advocated by the French delegates, but the general opinion was in favour of a substitution of an actual word rate. Such being the case, it became their duty to endeavour to carry out that intention in the most efficient manner for the interests both of the public and shareholders. He had only just returned from France, where he found that the operation of the word-rate had led to a considerable increase, both in receipts and in the number of messages sent. With an increase of business they must, of course, look to an increase in the expenditure, as a large additional number of messages would mean an increased number of clerks and instruments, and the probable use of the duplex instruments for many of their lines. In any case, they were not likely to require new wires for many years to come, and, when they did, there was an ample reserve fund to supply them from.—Mr. Capper seconded the motion, which was carried unanimously.—After the re-election of the retiring directors and auditors, the meeting closed with the usual compliment to the chairman and directors.

THE NEW ATLANTIC CABLES.—The *Faraday* is at Messrs. Siemens Bros.' Works, Charlton, taking in 1,000 miles of the ocean section. She is expected to make three trips before France and America are directly connected by wire. Telic Journal Aug 15 1879

THE RESERVE FUNDS OF THE CABLE COMPANIES.

Telic Journal Aug 15 1879

RECENT occurrences in connection with submarine cable enterprises have had the effect of directing the attention of all thinking men, interested therein, to the future of our submarine cables, and also to the present state of the reserve or renewal funds of the various companies.

It is thought by some of our leading practical electricians, that, in a few years, nearly all existing deep-sea cables will have become useless for telegraphic purposes; and others estimate that the life of these electrical conductors will endure for ten or even twenty years yet. Whatever length of time they may last, and this will vary according to the kind of cable and the ground on which it is laid, it is certain they are at present anything but permanent property. Many hundreds of miles of cable have already become totally useless, and without going much into details we may mention that of the seven cables laid across the Atlantic some are quite defunct, while as we are writing, two are in need of repair, and only two are left to do the whole message traffic from Europe to the United States and the Dominion of Canada.* As a general rule, cables laid in shallow waters are very liable to breakage, but, on the other hand, they are easily repaired. With deep-sea cables, although faults are comparatively unfrequent, the repairing is almost impossible owing to the outer covering and sheathing becoming weakened by decay. Last year an expedition composed of the s.s. *Seine* and s.s. *Calabria* failed to repair the 1866 (Atlantic) cable, and returned to this country on the 27th July, 1878. "The failure was caused by oxidation of the iron wire and decay of the hemp of which the outer covering of the cable consisted." So stated the report of the Anglo-American Telegraph Company.

It may be urged that cables will eventually be made more lasting, or that they may be made much cheaper, so as to permit of total renewals at comparatively frequent intervals, or it may be possible to obtain more sensitive instruments to enable work to be done after faults have shown themselves; but so exquisitely sensitive are the instruments now used that we fancy little can be hoped for in this direction.

Having considered to some slight extent the durability of the cables, the next point which demands notice is that of the reserve or renewal funds of the various companies. Taking the amount of the capitals together of four of the principal companies, having mostly submarine cables rather than land-lines, and the bulk of whose capital is invested in the sea, we find it to reach the considerable sum of over £15,360,000, whilst the reserve funds of the same companies also added together, amount to £731,659.

It cannot be said that directors are to blame for paying excessive dividends; for, with the exception of three companies, two of which pay 6 per cent., and the remaining one 17½ per cent., none of the companies pay over 5 per cent., and two or three pay nothing at all on the ordinary shares.

Nor can it be maintained that the reserve funds are at all adequate to complete renewal, for, doubtless, directors see as well as we do that, unless the receipts increase very remarkably, there is little likelihood of their being able to add any adequate amounts to the reserve funds, and at the same time satisfy their respective shareholders with dividends. The question then arises,—if the traffic returns do not increase, what is to become of those enterprises where no sufficient allowance has been made for renewal? Are they to lapse, or will the Government step in, and, for the sake of retaining our telegraphic communications with the rest of the world, and particularly with our colonies and foreign possessions, subsidize and sustain them, or, purchase existing rights, and, relaying the cables where necessary, work them itself?

The question is one of vast and ever increasing interest, alike to directors, shareholders, electricians, and all engaged in connection with submarine telegraphy—to the whole world, we may say—and the more the directors are aided in their difficult task, by the shareholders, the better will it be for all concerned, and particularly for the shareholders themselves. It would be living on in a Fool's Paradise not to look this serious matter boldly in the face. The Trust companies holding telegraphic securities must also necessarily be affected by whatever affects the success of those companies whose securities they possess.

* Since writing these lines, communication by a third cable has been restored.

THE NEW CABLE STEAMER.

Telic Journal Aug 15 1879

A FINE new cable steamer, built to order for Messrs. Siemens Brothers, was launched from the yard of the makers, Messrs. C. Mitchell and Co., Low Walker, Newcastle, on Tuesday, August 5th, in presence of a large number of spectators, including a distinguished company of ladies and gentlemen from France. The vessel is named the *Pouyer-Quertier*, after the well-known French statesman, who occupies the position of Chairman to the New Compagnie Français du Telegraphe à New York, in whose service she will be for the future engaged as a repairing ship.

Although much smaller, the new vessel bears in many respects a resemblance to her predecessor, the well-known cable steamer *Faraday*, also built by Messrs. C. Mitchell and Co., for Messrs. Siemens Brothers, about five years ago, and which has gained the reputation of being one of the most successful vessels afloat. Like the *Faraday*, the new steamer has twin screws, is fitted with rudder at each end, and has bilge keels of a special kind. There are on board two principal cable tanks, and sundry small supplementary tanks for coiling and stowing the different descriptions of cable. Her whole form and structure are unusually strong; and although bearing the highest class both of the English Lloyd's and the French Veritas, she is even stronger than required by these societies. The vessel is built with a curved bow, on which will be fitted a projecting girder with a swivel cable sheave, a similar sheave being also fitted at the stem. On the deck will be placed very powerful machinery of the latest and most improved description for "laying" and "picking up" cables. Arrangements will also be made for steering the vessel both by steam and by hand, and throughout she will be fitted with a complete system of telegraphs. This is an appliance indispensable for such a ship, as it enables those in charge to handle her in the promptest possible manner—a consideration of such vital importance in cable-laying. Taking it as a whole, the *Pouyer-Quertier*, embracing all improvements suggested by the extensive experience of Messrs. Siemens Brothers and their staff, may be considered as complete a vessel of the class as it is possible to produce. The machinery consists of a pair of compound surface-condensing engines, manufactured by Messrs. Thomas Clark and Co., of Elswick, including all the latest improvements in marine engineering, and capable of propelling the vessel at the speed of 10 knots per hour on the most moderate consumption of fuel. The dimensions of the steamer are: Length over all, 260 ft.; beam, 36 ft.; depth, 24 ft. 4 in.; and she will have a burthen of 1,800 tons. As the vessel left the ways, the christening ceremony was gracefully performed by Miss Siemens, daughter of Mr. Carl Siemens, who himself was present as the representative of his firm.

aux docks de Keesham à Plymouth ce qui reste du câble embarqué avec tant d'enthousiasme deux mois plus tôt.

Des hommes d'un génie vulgaire auraient essayé de sauver l'entreprise en vendant les débris du câble transatlantique à quelque compagnie sous-marine. Mais M. Cyrus Field trouve des arguments énergiques pour ranimer l'esprit des actionnaires qui lui avaient confié leur capital. Il les décide à faire une nouvelle émission d'actions.

Pendant toute la durée de l'hiver, M. Whitehouse et les électriciens s'occupèrent nuit et jour à expérimenter les moyens d'accélérer la vitesse des signaux transmis à travers les restes du câble et à perfectionner les moyens de recevoir les messages. Mais, hélas! on ne put arriver, malgré les plus grands efforts, qu'à une vitesse de quatre mots par minute. Encore, pour obtenir ce résultat si important, il fallait avoir recours à l'étincelle d'induction!

Il était certain que l'accident si funeste qui avait interrompu la grande opération était uniquement dû à un défaut dans l'appareil destiné à servir de frein.

Les efforts que l'on fit, après avoir constaté ce fait capital, conduisirent à imaginer le frein automatique d'Appeld, appareil dont les services ont été si bien appréciés qu'il est encore en usage et ne sera point sans doute remplacé.

La machine pour lâcher le câble et toutes les parties du système des mécanismes à vapeur dont le concours est nécessaire, reçurent également les plus notables perfectionnements.

Aucune des péripéties ni des accidents de cette nouvelle campagne n'avait été perdu.

Le *Niagara* et l'*Agamemnon* partirent de nouveau pour se séparer du milieu de l'Océan.

Mais avant de faire voile l'un vers Valentia, l'autre vers Terre-Neuve, les deux steamers devaient avoir été rattachés par une soudure unissant les deux bouts du câble dont chacun portait une moitié.

L'idée était simple et fort rationnelle, mais lorsqu'il s'agit de la mettre à exécution, les opérateurs rencontrèrent des difficultés inouïes dont le détail nous occupera une autre fois.

On eût dit que la nature accumulait à ce moment solennel tous les obstacles, et que le génie de ces solitudes déchaînait les tempêtes avec autant d'acharnement que celui qui cherchait, suivant Camoëns, à arrêter Vasco de Gama.

Il fallut s'y prendre à trois reprises pour que la soudure fût faite d'une façon, hélas! bien peu solide, et que les deux navires s'éloignassent l'un de l'autre comme il avait été convenu.

C'est le 6 août 1858, grand jour dans l'histoire de la civilisation, que les premiers messages furent échangés entre l'Angleterre et l'Amérique. La joie qu'excita le succès d'une entreprise qui semblait tellement dépasser les forces humaines, ne se borna point à la race anglo-saxonne. Elle s'étendit même aux nations qui n'avaient pris aucune part à la grande entreprise.

La France, qui ne connaît même point le sentiment de jalousie, si développé chez une nation voisine, se distingue par son enthousiasme. Si l'on en excepte certains physiciens de l'Académie des sciences, un élan pour ainsi dire universel s'empara du public parisien.

Mais ce triomphe n'était pas destiné à durer; il devait être bientôt troublé.

En effet, après avoir parlé pendant vingt-six jours d'une façon de plus en plus lente, de plus en plus pénible, le câble de 1857 refusa de dire un seul mot.

Le nombre des télégrammes échangés avait été de 400, chiffre insuffisant pour assurer autre chose qu'une recette dérisoire, mais assez important pour que le succès fût complet au point de vue scientifique.

Quelque redoutable que fût l'autorité de M. Babinet, elle n'était pas suffisante pour contrebalancer celle des faits accomplis.

Heureusement les progrès de la télégraphie sous-marine avaient été si grands que les objections des savants n'avaient plus de valeur sérieuse, même en présence d'une interruption qui semblait donner si complètement raison à leurs adversaires, d'autant plus redoutables qu'ils se bornaient à prétendre que le câble qu'on avait tant de peine à poser ne durerait pas, qu'il serait même brûlé infailliblement par les courants de grande tension que l'on serait obligé d'employer.

M. Cyrus Field parvint à faire comprendre aux capitalistes qu'il fallait réunir un second capital pour sauver le premier. Il faut ajouter qu'il appuyait ses raisonnements sur l'étude sérieuse, approfondie, complète des causes qui avaient amené le sinistre et qu'il présentait en même temps des moyens qui paraissaient sûrs pour triompher de si grandes difficultés.

Il insistait sur la marche irréprochable de câbles qui avaient déjà un développement assez considérable pour que les critiques de MM. Babinet et consorts pussent s'y appliquer si elles étaient fondées. Il faisait comprendre que l'énergie des courants employés n'avait rien que de très-relatif, et qu'il était excessivement facile de concevoir que leur faiblesse diminuerait au fur et à mesure des progrès de l'électricité. Il ajoutait même qu'en augmentant la conductibilité du câble on arriverait à diminuer les résistances et par conséquent l'énergie du courant nécessaire pour faire parler les appareils connus.

Enfin, il avait eu l'idée d'employer à la nouvelle pose le *Great Eastern*; ce navire géant qui pouvait porter dans sa cale le câble électrique tout d'une seule venue, et qui semblait avoir été construit providentiellement pour permettre aux deux moitiés de la race humaine de se réunir d'une façon définitive, malgré la profondeur des abîmes de l'Océan.

La réussite de cette opération gigantesque, aussi importante pour l'humanité que les conquêtes de César et d'Alexandre, restera comme un exemple mémorable des résultats que peut obtenir l'énergie persévérante quand elle est appliquée à une noble et grande pensée. Cette épopée scientifique n'est-elle pas digne de trouver son Homère tout aussi bien que le siége de Troie?

Le touage par câbles, sur les canaux américains.

Tout le monde connaît le touage tel qu'il s'opère sur la Seine, par exemple, au moyen d'une chaîne noyée au fond du fleuve et accrochée aux deux bouts, sur laquelle se hale le bateau-toueur, au moyen de treuils à noix ou de tambours à encoches.

Un système de touage analogue est en usage en Amérique, particulièrement sur le canal Erié, au moyen d'un câble métalli[que] noyé au fond du canal sur toute sa longueur et attaché à ses deux extrémités. Les remorqueurs, dont chacun a à traîner une flotte de bateaux, sont pourvus de machines qui donnent la puissance à l'organe moteur. Celui-ci a la forme d'un grand tambour dont la circonférence est pourvue d'une série de cellets mobiles qui forment une gorge continue pour y loger le câble; ces cellets mobiles sont construits de telle sorte qu'ils se ferment sur le câble lorsque le tambour tourne et le tiennent serré avec une force proportionnelle à celle qui agit sur le câble, par suite de la tension que lui imprime la charge traînée. Le câble qui se lève du lit du canal entre sur le bateau par la proue et est conduit par des poulies-guides jusqu'au tambour moteur monté sur le pont du remorqueur : si la machine est mise en train, le tambour tourne et la flotte de bateaux est traînée. Le câble redescend à l'eau par l'étrave de derrière.

Le rapport fait sur le trajet assez court de 42 milles (70 kilomètres), qui sépare Buffalo de Middleport, constate les bons résultats obtenus par ce système.

La vitesse était trois fois plus grande que celle que peut procurer la traction animale et on menait, sans plus de dépense, sept fois plus de marchandises. La plus grande charge fut de sept bateaux de canal, chargés de 1.499 tonnes de charbon, ce qui correspond à la charge de 150 wagons. Le fonctionnement du mécanisme était très convenable.

La Compagnie fondée pour l'exploitation de ce système sur le canal Erié se nomme *N. Y. Steam Cable towing Company*, et on dit qu'elle a déjà traité pour la construction et la mise en place de 300 milles (500 kilomètres) de câble d'acier fondu et pour la construction d'une flotte de 13 bateaux remorqueurs (1).

Ces excellents résultats développeront rapidement en Amérique ce système que les ingénieurs du Nouveau-Monde ont emprunté à la Belgique, où il est depuis longtemps en usage. — (*Engineering and mining Journal.*) La Correspondance Scientifique Sept 16 1879

Iron, Sept. 1881

ELECTRICITY, TELEGRAPHY

NEW CABLE BETWEEN TRIESTE AND CORFU.—Messrs. Erlanger, of Paris, have just obtained the necessary authority for laying the submarine cable between Trieste, in Austria, and the Island of Corfu, as well as the proprietary right of the said cable for a period of twenty years. The new cable will facilitate telegraphic communication between Austria and Egypt. The cost is stated to be estimated at one million florins.

THE ELECTRIC LIGHT FOR RIVERS.—Among the latest uses to which it is proposed to put the electric light on the other side of the Atlantic is the illumination of rivers to permit the rafting of logs at night. The Muskegon Boom Company will be the pioneer in this direction. In Baltimore experiments have been made with a view of illuminating water at night to a depth of 200 feet. Such a means of illumination, it is believed, would be of great service in searching for lost treasure and drowned persons, in raising wrecks, removing torpedoes, and in other subaqueous labours.

THE JAMIN CANDLE.—M. Jamin has made a considerable advance in the arrangement of his electrical candle. He encloses his carbon loop in a carefully closed vessel containing air. The electric action at first produces the combination of the oxygen and nitrogen of the atmosphere, and the usual coloured vapours are seen; these are soon destroyed by the oxygen combining with the carbon, nitrogen and carbonic oxide alone remaining in the glass globe. The phosphorescent arc then becomes quite fixed, giving light of a greenish-blue tint. Each candle by this arrangement lasts 160 hours.

TELEPHONIC COMMUNICATION.—The use of the telephone has been adopted on the system of the London, Chatham and Dover Railway Company, and the office of the superintendent at Victoria has now been placed in immediate communication with the Holborn Viaduct, with Loughborough Junction, where there are large sorting and make-up sidings, and with Wandsworth Road, where are the head-quarters of the locomotive and other departments. The goods manager's office at Victoria has also been connected with the goods depot at Blackfriars. The instruments in use are constructed on the Gower-Bell principle, which for some time have been used satisfactorily to connect the Victoria Station with the residence of the chairman, at West Wickham, near Beckenham.

THE ELECTRIC LIGHT AT SCARBOROUGH.—The Brush electric light has been utilised at the Scarborough Spa, and the lamps were put into circuit on Saturday last, the start being a brilliant display. The wide Esplanade was illuminated from end to end with seven 2000 candle-power Brush lights, suspended from iron posts, placed at intervals down the centre. It is stated that in each of the bandhouses a 2000 candle-power Brush light was hung from the canopy and replaced at a cost of 2d. per hour, gas costing 10s. per hour. The large concert hall was lighted by a central chandelier, consisting of five 2000 candle-power Brush lights. Altogether 16 lights were run on the one circuit, and from the one dynamo machine, which was driven by a Robey's semi-portable 12 nominal horse-power engine. The whole apparatus has been erected by Messrs. Hammond and Co., of London.

Guide pratique du télégraphe, par M. Louis Houzeau, commis principal des lignes télégraphiques.

Ce volume, publié par l'auteur-éditeur, 11, rue Rousselot (faubourg Saint-Germain), est arrivé rapidement à sa troisième édition. Il est orné de 70 figures et se compose de plus de 200 pages in-8°.

Les personnes qui veulent se former à la pratique des manipulations y trouveront tous les détails nécessaires à la manœuvre des appareils et notamment de ceux qui sont employés par l'administration.

Nous y trouvons un excellent tableau résumant les causes de troubles électriques et les moyens d'y remédier.

CHRONIQUE

M. Avrillon nous fait part d'une mésaventure qui lui est arrivée et qui mérite d'être signalée. Un de ses ouvriers manifesta le désir de voir le fonctionnement d'une petite bobine fabriquée par M. Loiseau, actionnée par une pile au bichromate du plus petit modèle. Après avoir reçu une commotion, cet homme n'a cessé de se plaindre, déclare qu'il ne pourra jamais plus travailler, fait des démarches en ce moment pour arriver à poursuivre son patron, et présente à l'appui de sa réclamation une épaule démise.

Il est matériellement impossible qu'une commotion donnée avec un appareil si faible produise le moindre désordre organique, et nous sommes certain que les tribunaux feront justice d'une pareille réclamation.

Si l'épaule de l'ouvrier s'est trouvée démise, si un docteur l'a envoyé à l'hôpital, c'est évidemment par suite de circonstances dans lesquelles l'électricité n'a rien à voir.

On donne depuis assez longtemps des secousses et des commotions sur les places publiques pour que M. Avrillon n'ait point à redouter les suites d'un si ridicule procès.

Nous signalons cette circonstance afin d'attirer l'attention de nos lecteurs sur le danger d'électriser des personnes de mauvaise foi.

NÉCROLOGIE

On nous annonce à la dernière heure la mort de M. Lamont, directeur de l'Observatoire de Munich, un des pères de la météorologie électrique. Nous donnerons dans un de nos prochains numéros une étude sur les travaux de cet homme célèbre et sur sa vie. Nous dirons déjà que les appareils qu'il employait étaient des *espèces de télégraphes électriques* dans lesquels les manipulateurs étaient absents.

CORRESPONDANCE

Nous recevons de M. Buchin, mécanicien à Bordeaux, la lettre suivante que nous nous empressons de reproduire :

Cette lettre intéressante peut être ajoutée à ce que nous disons d'autre part sur la multitude d'applications dont l'électricité est susceptible.

« Je viens vous signaler une application des machines Gramme ou autres qui, dans l'état actuel, peut trouver de nombreuses applications. M. Ferdinand de Lesseps pourrait trouver à cette application un auxiliaire très-puissant pour le percement de l'isthme de Panama.

« Je lui conseillerais, dans le cas où il réaliserait son capital, de prendre comme moteurs des machines Gramme qui conviendraient très-bien pour actionner ses perforeuses.

« L'emploi de l'arbre flexible, appliqué directement sur l'arbre des machines dynamo-électriques, ferait de cet appareil un instrument très-précieux, surtout par la facilité de son maniement : des moteurs fixes enverraient à grande distance le courant nécessaire pour actionner les perforeuses électriques. »

L'électricité se prête à merveille à obtenir ce résultat.

Si les travaux de percement de l'isthme de Panama doivent s'exécuter, ce qui est devenu douteux, en ce moment, nous aurons occasion de revenir sur les moyens pratiques de le réaliser à peu de frais et d'une façon absolue.

Nous recevons, en ce moment, un excellent traité par M. Barbe, officier d'artillerie, qui s'occupe exclusivement de cette importante question.

Pour juger des développements qu'elle est susceptible de prendre, nous nous contenterons, aujourd'hui, d'indiquer le sommaire de différentes applications dont s'occupe le savant auteur : la culture à l'aide de la dynamite, la destruction du phylloxera par son intervention, l'abattage des arbres et la rupture des pièces de fer, la destruction des ailes de pont, le creusement des bassins dans les ports de mer, la construction des galeries de mines, l'ouverture de la banquise du Pôle Nord, etc., etc.

La Cage de Faraday

Malgré l'efficacité incontestable des paratonnerres, l'expérience prouve que la protection qu'ils donnent n'est pas radicale et absolue. En effet, des effets électriques peu dangereux, mais sensibles, se manifestent dans leur voisinage.

Il n'y a qu'un moyen d'être complètement à l'abri, c'est de s'enfermer complètement dans une cage en cuivre, dont les barreaux sont suffisamment rapprochés et qui est en communication avec le réservoir commun.

L'efficacité absolue d'un pareil abri a été démontrée il y a longtemps par Faraday, à l'*Institution*

108

Ocean Telegraph Cables.

So. Aus. Nov 22 1879

In a recent lecture by Mr. Wm. H. Preece, he says: The deep sea portion of the Cape cable, while it differs to a certain extent from the Atlantic types, is still deficient in that absolute durability which all cables ought to have. In fact there is room for invention in this direction. Generally, one notices that, where there is a want, some one will spring up with an invention to meet that want. Here is a want that has existed for many years, but no one has invented a cable which can be said to be perfectly adapted for its purposes; so that, if any one here is of an inventive turn, let me recommend him to try his hand at inventing a cable which will give us all the requirements needed.

This cable to the Cape has one peculiarity in which it differs from any others. Now, among the various accidents to which cables are subject, there is one due to the existence of life at the bottom of the sea. We know that in different seas there are certain little insects, sometimes *Teredos*, sometimes *Xylophaga*, sometimes *Limnoria*, and others of very hard names, which have a peculiar liking for gutta percha. These little *teredos* attack us on sea as well as on land, and the trouble they cause us is sometimes immense. We suffer from them very much on the Irish coast, where the little wretches have found their way to the gutta percha, and have there scored and figured it in a very curious way, samples of which you will see on the table.

To put a check to their boring instinct, the Telegraph Construction and Maintenance Company, who made the cable which is being laid to the Cape, but which was originally intended for Australia, have surrounded the gutta percha with a wrapping of brass; and if any of these boring insects abound in any portion of the line where this brass wrapping is used, I have no doubt that the brass will be too much for them, and that they will find themselves terribly beaten in making any attempts to get at the gutta percha.

It is found that these little animals do not exist at greater depths than 100 fathoms, and, therefore, in the deep sea portion of this cable the brass wrapping will not be found.

There are a great many accidents to which submarine cables are subject. One of the principal is that of a ship's anchor, and it was the disturbing element of a ship's anchor that prevented me from having the pleasure of being before you last Monday. On the table is a piece of cable which has been taken out of that crossing the River Humber. The cable which crosses this river is one of the most important that we possess, and for that reason one of the strongest kind of cable ever made was laid down. In the Postal Telegraph Department we have no less than 62 cables, and their aggregate length of 1,221 miles contains a total of 3,809 miles of wire. To cross rapid streams and important rivers strong cables are used, and to cross the Humber, which during spring tides runs at the rate of six to seven knots an hour, a cable of the strongest type was used; yet it had not been down six weeks when a ship got hold of it, and the cable was caught by its anchor. The heavily laden schooner riding on a strong tide, with its anchor attached to the cable, brought to bear an enormous force, and, perhaps owing to the construction of the cable, this force would not be equally divided among the outside protecting wires, and thus one wire, bearing the greater strain, gave way, followed by the snapping of a second, and so on till the whole cable was severed in the straggling and tangled manner that you see, which is very different from its symmetrical form when first laid. This break occurred in a very nasty stream, where the cable was so buried in mud that I could not find it; and I was despairing of being able to give even a second lecture here, when a happy thought occurred to me. I had spent a whole day in grappling after this cable, trying over and over again, and yet never getting near it, when it suddenly came into my mind that Shakespeare makes Bassanio say—"In my school days, when I had lost one shaft, I shot his fellow of the self-same flight, the self-same way, with more advised watch, to find the other forth; and, by adventuring both, I oft found both." So, knowing that a ship had dropped its anchor over the cable, I thought we would drop our anchor too, and we did, and waited a whole tide, and when we hauled the anchor up there was the cable.

The chief cause of accidents to cables, next to that of anchors, is probably due to abrasion of the cables on rocky bottoms. The bottom of the sea is frequently of an undulatory nature, and the cable remains suspended from point to point, and at such points the wire becomes chafed and worn away, and speedily decays. I am sorry to see that the time at my disposal has gone so rapidly that I cannot particularize to you many of the different causes that lead to the destruction of cables, not only abrasion, not only accidents in paying out, but accidents that exist afterward; for instance, a whale once caught a cable in the Persian Gulf and broke it; a shark's tooth has been found imbedded in a cable, and a sinking ship has caused damage to a cable.

Sometimes the cables rest on corrosive stones, copper ores, and ironstone, when corrosion sets in and causes the cable to speedily fail. Volcanic action sometimes damages cables, as also rock slips. In the Bay of Biscay, which is crossed by the Direct Spanish Company's cable, there is no doubt that such a cause has interfered with the cable on two occasions, curiously enough, interrupting the wire each time on the same day of the year. There is a peculiar shelving of the rock, and slips exactly equivalent to our landslips take place at intervals.

Icebergs, too, from the North Atlantic, frequently carry large pieces of rock, which fall to the bottom when the iceberg thaws, and in their descent are liable to fall across a cable and damage it.

There are also faults due to imperfect joints, due to accidents that pass inspection during the process of manufacture, but which slowly develop themselves after submersion or lapse of time.

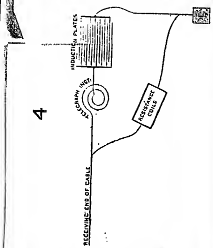
Lightning, earth currents, and things of that kind affect cables, but, nevertheless, the eye of the telegraph engineer is constantly watching these circumstances as they happen, and he tries to bring to bear upon them all the power and thought he possesses; and the result is that, by slow experience, the cable of the present day is very superior to that used in the early days, and the improvement has been equal to the advance, which, I hope I have been able to show you, has been made as regards the insulators and iron wire.

NOTES ON MR. WILLOUGHBY SMITH'S PAPER UPON "THE WORKING OF LONG SUBMARINE CABLES."

(CONTINUED FROM P. 238.)

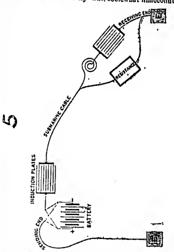
Electrician. Oct 11 1879

Mr. Willoughby Smith gave in his paper five diagrams, which we here reproduce, referring to arrangements for signalling through long cables which were patented by Mr. Varley in 1862. In Fig. 4, it will be seen that the receiving end of the line is con-



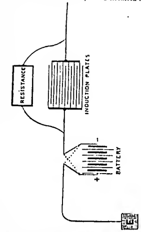
nected to earth through a resistance coil (which was stated by Mr. Varley to be more effective when wound on a large iron core) and that it is also connected, through the receiving instrument, with one side of a condenser of which the other side is connected to earth. This arrangement is of interest as being, we believe, the first in which the use of condensers for cable signalling was suggested, and also from the fact that in it an evident attempt is made to utilise the "inverse current on making contact," and also the coil current, or "direct current on breaking contact." It should be borne in mind that, when these arrangements were devised, the impression everywhere prevailed that an Atlantic cable could be worked only by very powerful currents of electricity. And an ingenious mind, acquainted with the facts in relation to what Faraday termed "the induction of a current on itself," might readily suppose that the arrival current would be retarded, or arrested for a minute space of time, by the resistance coils indicated in the figure, whilst it would freely pass through the receiving instrument to charge the condenser, and thus give a signal; and further, that this signal would be "sharpened" by the subsequent discharge of the condenser through the coils in question, serving also to discharge the cable. But, as the writer of these notes discovered to his cost, in a lengthened experimental trial of some proposed improvements in signalling which appeared *primâ facie* to be very efficacious, the effect of electro-magnetic retardation is not exhibited when a coil is placed, as shown, at the receiving end of a long submarine line. This is due to the very *gradual* rise of tension at the distant end of a conductor of high resistance and charging capacity, when such a conductor is charged from a source at the near end. For the effects of electro-dynamic induction to be strongly manifested, the current must be suddenly produced and suddenly arrested—a fact which the makers of dynamo-electric machines, as well as the makers of induction coils, would do well to keep in view. Moreover, by the introduction of Sir W. Thomson's mirror galvanometer as a signalling instrument, cables became readily worked by what Mr. Varley once termed the "ghost of a current;" and such a current, as Mr. W. Smith pointed out, is totally inadequate to produce perceptible electro-magnetic induction effects.

In Fig. 5, we have the same arrangement at the receiving station; whilst at the sending station the line is insulated from earth by a condenser. Here Mr. Varley comes very near indeed to the present system of working long cables, in which the line is normally insulated from earth. We learn from Mr. W. Smith's paper that Mr. Varley was, somewhat unaccountably,



under the impression that the condenser would be useless without the adjunct of the resistance through which, together with the receiving instrument, it is circuited.

In Fig. 6 the condenser at the sending end is circuited through



a resistance, presumably possessed of electro-magnetic inertia. We must confess that we cannot perceive the object of this arrangement, the results of which would appear to be from every point of view undesirable. In effect, the resistance would in no wise facilitate the sending of a current to line; whilst the coil current would oppose the discharge of the latter, by contact with earth at the sending end, or the reversal of the current.

In the next figure the object seems to be the sending of a current to line for a very short period of time, *i.e.*, until the magnetic inertia of the induction coil is overcome, or its inverse cur-

Ailkand's Schreib-Telegraph für submarine-Kabel.

Der Zeitschrift? Nov. 1879

Die Spiegel-Galvanometer, die bis jetzt fast ausschliesslich auf langen unterseeischen Kabeln zum Telegraphiren benutzt werden, haben den Uebelstand, dass sie die übermittelten Schriftzeichen nicht bleibend wiedergeben. Im Interesse des Dienstes ist es aber sehr wünschenswerth, dass die Zeichen nicht allein sichtbar, sondern auch dauernd lesbar ankommen.

Die ersten Versuche zur Construction wirklicher Schreibapparate, welche auf den langen unterseeischen Leitungen Verwendung finden konnten, sind nach Zetzsche's Geschichte der elektrischen Telegraphie (S. 148) von Siemens mit dem elektro-dynamischen Relais auf dem Kabel des Rothen Meeres angestellt worden. Ein ganz origineller Apparat für Unterseekabel ist der Heberschreibe-Apparat von Thomson, welcher auf dem englisch-amerikanischen Kabel benutzt wird. Dieser Apparat hat seinen Namen von einem kleinen Heber, welcher mit dem kurzen Ende in ein Tintenfass eintaucht und mit dem langen Ende dem Papierstreifen gegenübersteht. Durch eine Reihe elektrischer Entladungen wird die Tinte in Form feiner Tröpfchen auf den Papierstreifen abgesetzt und dadurch die Morseschrift wiedergegeben. Die Schrift ist spitz, zickzackig, oberhalb, beziehungsweise unterhalb der Mittellinie des Papierstreifens und es bedeuten die oberen Spitzen die Striche, die unteren Striche die Punkte des Morse'schen Alphabetes, bezw. umgekehrt. In ähnlicher Weise sucht Siemens mit seinem Russschreiber die Morseschrift wiederzugeben.

In neuester Zeit nun hat Ailkand einen Schreibe-Apparat konstruirt, der in einfacherer Weise die Schriftzeichen dauernd erzeugt. Derselbe besteht nach "Ann. Télégr." aus zwei hintereinander geschalteten Elektromagneten mit je zwei Rollen, welche so gegen einander stehen, dass zwischen je zwei Rollen ein kleines Magnetstäbchen den Polen der Kerne gegenübersteht. Diese Magnete werden von einem Aluminiumdraht getragen, dessen unteres, mit einem eisernen Knopf versehenes Ende in ein eisernes Quecksilbergefäss mündet.

LE TÉLÉGRAPHE DE LA RÉUNION

L'Électricité

La ligne télégraphique du Cap

Nous apprenons par le journal le *Temps*, si bien renseigné sur toutes les questions électriques, que le gouvernement anglais a passé un contrat avec la compagnie de l'*Eastern Telegraph*. La garantie accordée est, paraît-il, d'un minimum de recette annuelle de 60.000 livres sterling (1.500.000 francs).

La Compagnie, maintenant, est chargée de la fabrication de la ligne sous-marine d'Aden à Zanzibar.

La fabrication en sera poussée avec une si grande activité que la pose doit être terminée au 1er novembre.

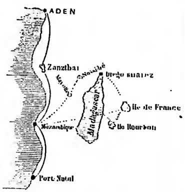

Diagramme montrant le réseau télégraphique des îles Mascareignes (1).

Comme nous l'avons déjà dit, le réseau colonial s'étend de la ville du Cap à Port-Natal, autrement dit Durban, port important de l'océan Indien.

Le câble qui rattachera cette ville à Zanzibar s'est trouvé heureusement disponible.

En effet, les colonies autrichiennes l'avaient fait construire pour assurer une seconde communication avec l'Europe.

Elles ont eu le patriotisme de laisser ce magnifique câble à la disposition du gouvernement britannique, de sorte que la pose sera terminée au premier juillet. Cette ligne nouvelle ira de Port-Natal à Zanzibar en passant par Delagoa Bay et Mozambique, capitale de la capitainerie générale du même nom. Il en résulte que la perspective à laquelle nous avions fait allusion se trouve réalisée. Le câble sous-marin passe à proximité de nos établissements des Comores. Il peut être rattaché à l'île Bourbon d'une façon simple et sûre, si nous formons un établissement permanent au cap Diego Suarez où existent déjà, si nous ne nous trompons, des factoreries françaises.

(1) Aden est en Asie et non sur la côte d'Afrique comme l'indique par erreur le diagramme.

111

Un des résultats de cette initiative serait de mettre en valeur nos établissements dispersés sur les flancs de la grande île qui appartient théoriquement à la France! On pourrait également rattacher par un câble spécial l'île Bourbon à l'île de France, dont la population créole est encore de cœur toute française.

Une autre voie pourrait être construite comme on le comprendra en jetant les yeux sur la carte qui accompagne cette notice. Qu'est-ce qui empêcherait par exemple de poser hardiment le câble dans l'île de Madagascar, où l'importance de nos intérêts commerciaux s'accroît de jour en jour?

En effet, la Chambre des députés est saisie en ce moment d'un projet de loi rédigé de concert par le ministre des affaires extérieures et le ministre de la marine pour établir à Tananarive une juridiction consulaire au profit de nos nationaux.

La résistance des Hovas, si elle se produisait, est du genre des obstacles qui doivent être surmontés par les armes, car le *droit au câble* existe pour toutes les nations civilisées, et l'on ne doit laisser sous aucun prétexte la barbarie opposer un stupide *non possumus* à la civilisation.

Les journaux de Londres nous apprennent que le câble destiné à cette grande opération coûtera environ 20 millions de francs. Le premier navire destiné à opérer la pose de Zanzibar à Port-Natal aura quitté l'Angleterre au moment où ces lignes seront sous les yeux de nos abonnés.

La subvention de la Compagnie Orientale sera payée en partie par le gouvernement impérial d'Angleterre, par le gouvernement de Natal et par le gouvernement Portugais intéressé à l'établissement des deux stations de Mozambique et de Delagoa Bay.

La ligne étant posée le long des côtes, on suppose que l'entretien sera excessivement peu coûteux.

W. DE FONVIELLE

A NEW IRISH CABLE.—In consequence of the frequent failures of existing cables and the expected increase of Irish telegraphic business, the Post-office authorities have determined upon increasing the means of communication by the laying of a new cable, containing a core of four wires. Operations have already commenced, and it is anticipated that the new line will be completed early in January next.

THE FRENCH ATLANTIC CABLE.—M. George Van Chauvin is at Ottawa on behalf of the new French Cable Company, with a view to ascertaining what steps are necessary in order to effect a landing on Canadian territory. The Dominion law provides that any British company shall have the right to land cables upon taking out letters patent for that purpose. This appears to preclude the French company; but should it be so interpreted by the Ottawa authorities, no obstacle is likely to be put in the way of conceding the privilege by fresh legislation. As soon as the application for power to effect a landing in Canada is granted, the company propose to lay a cable from the Island of St. Pierre de Miquelon (which is the only vestige that remains of French domination in North America) to a point either on Cape Breton or the Nova Scotia mainland, near the Gut of Canso, and thence to connect with the telegraph systems of the Dominion. M. Van Chauvin is accompanied by Baron de Cambrey.

Télégraphie sous-marine

CHRONIQUE

L'Électricité

Le steamer *Dacia* vient d'arriver à Alger, apportant dans ses cales le câble destiné à rattacher une seconde fois Marseille à la métropole de nos établissements sur la côte septentrionale de l'Afrique.

Nous devons féliciter de nouveau M. le ministre des Postes et Télégraphes d'avoir organisé une expédition si nécessaire au développement des relations télégraphiques avec la colonie.

Ajoutons que l'intention de l'administration est de réduire à 10 centimes par mot le tarif des dépêches, aussitôt que ce second câble aura été posé. Nous sommes certain que le trafic augmentera dans une proportion suffisamment rapide pour récompenser l'administration du courage avec lequel elle applique, dans cette occasion importante, les principes les plus sages de l'économie politique.

La pose a commencé à Alger, le 10 août, en présence de M. Albert Grévy. Un punch a été offert à l'honorable gouverneur de l'Algérie, à bord du navire anglais.

Il n'est pas inopportun de rappeler à nos lecteurs l'histoire des mésaventures de l'ancienne administration algérienne, lorsqu'il s'est agi de la pose du premier câble algérien ; mais pour éviter des redites nous nous bornerons à les renvoyer à nos Tablettes historiques publiées à la fin du volume de l'an dernier.

Mais parmi les singulières fantaisies de l'administration à cette époque, il est impossible de ne pas citer l'acquisition, moyennant un quart de million, d'un steamer anglais, qu'on destina à la pose du câble, et que l'empereur Napoléon III baptisa lui-même du nom du *Dix Décembre*, appellation qui lui porta bonheur, comme nous le verrons une autre fois.

M. Reginald Forster, de Sainte-Catherine's Point Niton, île de Wight, publie dans le *Times* une lettre fort curieuse.

Il nous apprend que le second dimanche de septembre, à 6 h. 30 du soir, le steamer *Charles W. Anderson* fut obligé de jeter l'ancre pour éviter d'échouer. Sa position était excessivement critique et il fallait à tout prix faire venir de Cowes un remorqueur. Mais comme ce naufrage avait lieu un dimanche, le télégraphe postal ne marchait pas. Ne pouvant vaincre la résistance de l'employé, qui était un bon *sabbatarien*, on fut obligé d'envoyer un homme à cheval pour chercher le remorqueur, qui n'arriva qu'à une heure du matin.

Pendant tout ce temps, les marins du *Life-Boat* furent obligés de veiller dans le cas où un sinistre se produirait.

Une pareille marque d'ineptie de la part d'un télégraphiste ne saurait être trop énergiquement signalée.

La direction du câble transatlantique français a reçu d'Amérique une dépêche annonçant que le steamer *Faraday*, appartenant à la maison Siemens, a heureusement terminé l'immersion de la partie comprise entre les îles Scilly et le banc de Terre-Neuve.

L'opération a duré juste le nombre de jours qui avait été calculé, avant le départ du *Faraday*, comme étant nécessaire à son accomplissement.

A la date du 4 septembre, le *Faraday* s'occupait à installer une bouée sur l'extrémité du fil qui est encore au large de la grande île américaine.

Cette opération étant terminée, il s'est rendu à Londres pour prendre le câble de terre et la ligne qui doit joindre Terre-Neuve à New-York. Ce sont les deux sections à la fabrication desquelles nous avons assisté dans l'usine de M. Siemens, à Charleton, ainsi que nous l'avons rapporté.

Il y est arrivé le 16 septembre au matin, après s'être triomphalement acquitté de cette grande et importante mission.

Il reprendra la mer dans la première semaine d'octobre pour terminer l'opération simple et facile qui doit la compléter.

Nous enregistrons avec d'autant plus de plaisir ce succès de la Compagnie du câble électrique français, que des gens malintentionnés avaient répandu en Amérique le bruit que la pose avait échoué à cause des gros temps, et que le *Faraday* avait été obligé d'abandonner son câble en pleine mer.

Nous trouvons ce stupide *racontar* dans l'*Operator* du 1er septembre publié, du reste, à New-York, à une date où l'on n'avait pu avoir de nouvelles de l'expédition ; car c'était uniquement avec l'Europe que le *Faraday* se trouvait relié pendant cette opération.

Ces tentatives pour égarer l'opinion publique donnent une idée de l'importance qu'on attache par avance à l'intervention du câble français dans les relations télégraphiques entre les deux continents.

THE ENGINEERING AND MINING JOURNAL

[Oct. 15, 1881.

TESTING UNDERGROUND TELEGRAPH CABLES.*

By Dr. Brix.

In a paper read before the Electro-Technical Society of Berlin, Dr. Brix
describes in detail the methods adopted in practice of testing the under-
ground cables on the lines of telegraph under his direction. The tests
are made once a week. In measuring what the author calls the "copper
resistance," that is, the electrical resistance of the copper conductors,
great advantages are found in having several wires in one cable. In
such a case, the wires may be measured in continuous circuit, instead of
making use of an earth return. The importance of this in obtaining
exact measurements will be understood when note is taken of the dis-
turbing influences of polarization of earth-plates, and the working of
other lines having earth-plates at no great distance.

At the distant station, the several conductors of the cable are con-
nected together; at the place of measurement, the testing-room of the
home station, two of these conductors are connected with the Wheatstone
bridge, and the resistance of this wire circuit is measured in the usual
way. The battery is not in this case put to earth, but is in communica-
tion with the bridge, an arrangement which gives true results, even if
one of the conductors has a fault of insulation, for no loss of current
can then take place through the fault. When there is a fault of insula-
tion in each of two conductors, the case is obviously different; for if
these faulty wires were connected up to form a circuit, a leak would
occur from one wire to the other through the earth, and a false indica-
tion would be obtained. In such a case, the wires must be connected up
singly, care being had that a faulty wire be joined to a sound one.
When dealing with three wires, the resistance of these singly may be
easily found by the method of connecting-up in circuit here referred to.
Connection is first made between Nos. 1 and 2, then between Nos.
1 and 3, and lastly between Nos. 2 and 3. The last measurement
deducted from the sum of the two others gives twice the value
of No. 1, and this value deducted from the first two measure-
ments gives the value of Nos. 2 and 3. In a cable containing seven con-
ductors, seven circuits, made up in like manner, will be sufficient. But
in practice nine are formed; the additional labor occasioned thereby
is small, and more than compensated by the advantages gained. These
nine combinations are so chosen that out of any three of them three
circuits may be determined, and that a circuit, say No. 7, may be com-
mon to each of the three groups. From these nine measurements are
thus obtained three values of No. 7. Each of these values is deduced
from three independent measurements; and if these three values agree
one with another, there is strong presumptive evidence of their being all
correct. A further proof may be obtained by comparing the measure-
ments one with another, when these have been taken always in the same
order. The difference between two consecutive measurements must
always be about the same in amount. From the copper resistance
obtained in this way, after making a suitable reduction for the tempera-
ture of the room and the rheostats, the mean temperature of the under-
ground cable is deduced. The measured resistance of the conductors is
compared with a standard resistance at a normal temperature of 15°
Centigrade.

contained in the old saying of. It being a long lane that had no turning. They had travelled that lane for some time, and although they had thought they saw rays of light occasionally coming across their path, it must be admitted that all those bright hopes had gradually faded away, and they could only come to the conclusion that, looked upon as a field for telegraph enterprise on a commercial basis, the West India colonies were unprofitable. It was said that the man who waited long enough always got what he wanted, but, unfortunately, in their case, while they were waiting the cables on which they depended were running through their span of natural existence, and were approaching that decay which must end in the cessation of their operations, and, unfortunately, during their lifetime they had not been able to put by such reserves as were sufficient to relay or restore them when they ceased to work. With these facts staring them in the face, it was natural to ask, what was their policy? Were they to see their cables gradually dying out before their eyes, and to see the eventual loss—he did not say when it was to occur—of a great part of the capital sunk in the endeavour to connect the West Indian colonies with the rest of the world by telegraph, and were the colonies to be deprived—to lose, in fact, their communication with the home country, which in these days almost every colony of any size or importance thought it necessary to have? The only policy that they had—they had tried everything they knew of—was to continue their importunity with those who were so largely concerned in having a continuance of the system." He also remarked, "He had been struck with an article in the *Colonist* of Demerara, an article which contained, in the midst of a great deal of common sense and liberality of feeling, some reflections on the company which were not deserved. The article, he might say, did not entirely approve of the policy of the Government in this matter, but it traced the cause of their unfortunate position and their impecuniosity to their own folly and bad policy, and particularly in the matter of high rates. Now, those rates were fixed originally by the colonies themselves. The rate originally was for 20 words. Soon after the company was formed a very great concession was made by the company to the public of those colonies, for they diminished the minimum of 20 words to 10 words, charging only half the rate fixed for 20 words. It was very much less remunerative to carry a 10 word message at half the rate hitherto charged for a 20 word message. When the present board took office the 10 word rate was in force, and they found after working for two or three years with the system in complete order that there was not revenue enough to pay their working expenses, pay the small dividend they did on two or three occasions, and put by sufficient money for the renewal of the cables. They then applied for an increase of the rates, and the higher rates they were allowed to introduce had resulted in an increased revenue of £18,500 a year. If it had not been for that policy of theirs and that increase of rates, they would hardly have been in existence now, for there were many things they would have been perfectly unable to carry out. He thought it a pity, therefore, that people should have such an erroneous idea, and prejudice the minds of their fellow colonists in this manner." He then moved the adoption of the report and accounts, and the payment of the dividends recommended on the First and Second Preference Shares. Mr. William Ford, a director, seconded the motion. Mr. William Abbott thought that the Chairman had attached too much importance to the article in the paper he had referred to. He thought that the directors should go on and administer the affairs of the company as they considered best in the interests of the company. He would like to know, as the report was only to the 30th of June, whether the colony of Demerara had really deducted the subsidy. He thought it would be a very awkward time for that colony to be on bad terms with the company, looking at the very general rise which had taken place in everything the West India Islands produced. The Chairman, in reply to questions, said they had entered into a contract for picking up the *Investigator* for £14,500, and it was expected that the vessel and its machinery would be picked up for £16,000. They had had no offers from the underwriters with respect to the vessel, and the claim for the amount of the insurance was awaiting settlement at law. They had received information that up to the present Demerara had withheld the subsidy. The motion was then put and carried unanimously.

Eastern Extension, Australasia, and China Telegraph Company, Limited.—The twelfth ordinary general meeting of the shareholders of this Company was held on Wednesday, October 22, at the City Terminus Hotel, under the presidency of Mr. J. Pender, M.P. The report, an abstract of which appeared in our last issue, having been taken as read, the chairman said: Then before putting the resolution to the meeting for its adoption, I will, as usual, give you a few figures on the working of our system. As stated in the report, the gross receipts for the half-year ending the 30th of June, 1879, were £150,107, against, for the corresponding period of 1878, £135,482, showing an increase of £14,624. The expenses for the past half-year amounted to £65,509, against, for the corresponding period of 1878, £61,222, or an increase of £4,287. This is more than covered by the expenses of keeping three repairing vessels during the last half-year instead of two, as in the corresponding period of 1878, and by carrying an additional £1,000 to the maintenance ships' reserve fund. But for this a saving of about £2,300 would have been shown. The screw steamer, Edinburgh, has now, however, been sold, as stated in the report, for £10,000. The net revenue for the half-year under review was £84,597, in the corresponding period it was £74,260, being an increase of £10,337. Two interim dividends of 1¼ per cent. each, absorbing £49,937 10s., have been paid for the half-year, leaving a balance of £34,660 to be carried forward. As to the duplicate Australian cable, the first section of it was successfully laid and opened for traffic on the 16th of August last, and connected Malacca. This was done by arrangement with the Government of the Straits Settlements, who have to pay the company an annual subsidy of £1,000 for ten years. A considerable portion of the second section between Singapore and Java has been laid, and a vessel with the necessary cable to complete the section is now on her way to Singapore. We anticipate that the contractors will complete the whole work in the early part of next year. The articles of association state that in case of a vacancy in the auditorship it shall be filled up by an extraordinary general meeting. As, however, Mr. Ball's death took place so recently, the directors considered it unnecessary to call a meeting specially for the appointment of a successor, and therefore requested Mr. Ball's firm to complete the audit to the 30th of June. The vacancy will be filled up at the extraordinary meeting which is to be held at the conclusion of this meeting. Now, gentlemen, I have given you certain figures, or rather made certain comments, upon the report which you have in your hands. I may now say a few words, and those of congratulation, on the general improvement of our traffic. I have stated that up to the end of

the half-year ending 30th June last we have shown a net profit over the corresponding period of the previous year of £10,000. From that time up to the present I am glad to say that our traffic has generally been very successful indeed—in fact, I may say that we are having now the best traffics we have ever had, and this may be to a certain extent accounted for in two ways. There is the Exhibition going on at Sydney for the present month, and there is a general improvement in trade. I have very often said at these meetings that our telegraph system is a very good barometer of trade. With bad trade we suffer, with good trade it is quite remarkable the buoyancy that takes place, and I hope that the improvement which is now pretty well acknowledged to exist will be maintained. You know that we have always been told that any improvement was to come from America. Well, America is very rampant at the present moment, and that is also testified by the returns on the Atlantic cable system. I have often also said that the importance of duplicating your cable was very great indeed; and I may mention that while our cable has no interruption at the present time, yet, had we not laid down our duplicate system—or that portion between Singapore and Penang—we should have been at a standstill. The original cable is now interrupted, and the whole system would have been interrupted. Fortunately this duplicate was laid down in time, and we are reaping the benefits of additional security and also of the improved traffic. I am glad also to tell you that, with regard to the duplicate cable which we are under contract to have completed by the end of February next, that we were enabled, without any loss or sacrifice on our part, with the sanction of the Australian Government, to give the home Government evidence of our desire to help them in having the Cape cable established; and I am glad to say this, notwithstanding our helping them in this object, the duplicate system will, I believe, be completed very early next year, or nearly two months before the contract time (hear, hear). I am also glad to tell you that Colonel Glover has visited all our stations. He was absent from London for something like eighteen months, and he has been able to give us a report of the working of our system, and I am glad to say that this visit has been of very great good, as you can well conceive. Our young men like to see their managing director among them, and I believe that Colonel Glover's visit has been productive of very great good. We were also able to avail ourselves of his presence in Australia to carry to a successful issue the negotiations with the Australian Governments. To do this Colonel Glover had to get them into a spirit of harmony for the benefit of the whole, which is rather a rare thing to get done. Each thinks that he knows better than his neighbour, but in this particular business of the duplicate cable they seem to be pretty well in accord. Colonel Glover has travelled during the time he has been away something like 40,000 miles. I am also pleased to say that up to the present time the experimental system of sheathing our cables with a brass coating has been successful. With these remarks, gentlemen, I think that I have pretty well exhausted all that I have to say to you, except this—that, as you are all aware, an important conference was recently held in London of the telegraph representatives of every Government, certainly of Europe, which laid down certain laws. We had not a seat at that conference, but so far we have always felt that we have been fairly dealt with by the conference. There is, however, a difference of opinion among some of the merchants at the present time, who think that they have been more or less aggrieved by certain alterations that have been made. But I will only make this remark—that we have no power to alter what has been done. We have certainly the power of receiving communications from merchants who feel themselves aggrieved; but I would say to those merchants that, looking to the history of submarine telegraph progress, up to the present time they have certainly had the best of it (hear, hear). They have dealt with the code system to an extent that was never contemplated. Had the original prospectus of this company been carried out, we should have been paying you to-day probably 35 per cent. instead of 5 per cent., and, therefore, the merchants have no cause to complain. They have done all they could—they have used their utmost ingenuity. I do not blame them for this. I think it quite reasonable that they should have the greatest amount of traffic carried at the smallest expense; but, on the other hand, they must take care not to kill the goose that lays the golden eggs (hear, hear). If any merchant feels himself aggrieved I shall be very glad to meet him and discuss the question, and I am satisfied that I will show him that the greatest benefit of the system has been with him and not with the shareholders. With these remarks I beg to move the adoption of the report. The resolution is—"That the report and accounts of the directors now submitted be received and adopted." The Right Hon. W. N. Massey, M.P., the Deputy-Chairman: I beg to second that. After some further remarks as to the appointment of an auditor in the place of the late Mr. John Ball, and the report and accounts having been adopted, the proceedings terminated.

The Brazilian Submarine Telegraph Company, Limited.—The twelfth ordinary general meeting of the shareholders of this company was held Oct. 28th, at the City Terminus Hotel, Cannon Street, under the presidency of Viscount Monck, chairman of the company. The chairman, in moving the adoption of the report, pointed out that the revenue for this period amounted to £75,083 13s. 11d.; the working expenses to £13,452 14s. 4d., leaving a balance of £61,630 19s. 7d. To this is added £23,301 16s. 9d., the undivided profits to 31st December last, making a total of £84,932 16s. 4d. After deducting income tax (£832 11s. 9d.), there remains a balance of £84,100 4s. 7d. A third interim dividend, amounting to £16,250, has been distributed since the last accounts were presented, leaving the sum of £67,850 4s. 7d. for appropriation. The directors now recommend the declaration of a final dividend of 2s. 6d. per share, free of income tax, making a total dividend of 5 per cent. for the year ending 30th June, 1879, which will absorb £16,250, leaving a balance of £51,600 4s. 7d. Of this amount £50,000 has been placed to the reserve fund, increasing that fund to £227,437 8s., and £1,600 4s. 7d. carried forward. Upon these figures he (the chairman) thought it was not necessary to observe at any great length. The report and accounts told their own tale. The object the directors had in view was to frame their report in a perfectly intelligible form so as to enable a comparison of one year with another to be drawn at a glance. The receipts of the past half-year, compared with the corresponding half-year of 1878, showed an increase of £5,000. But it should be remembered that the war in South Africa had brought grist to the mill, and they had carried a considerable amount of news from Madeira. Added to this, there was also an increase of 15 per cent. in ordinary messages. The speaker then referred to the unfortunate agreement which existed between this company and the Western Brazilian Telegraph Company, but with the assistance of the legal adviser of the board he hoped to be able to mitigate the evil of this unfortunate agreement. If they succeeded in getting rid of that agreement the profits of the company would largely increase. It would also be

A GRAND INVENTION

Feby 3 1880

The Atlantic Cables Knocked in the Head.

A Hartland Frenchman the Inventor.

An Ocean Steamer Carries a Portable Telegraph, and at any Moment Can Telegraph Ashore, Even when in Mid-Ocean and Telephone Too.

EDISON BEATEN OUT OF THE MARINE FIELD.

Full, Special and Exclusive Details.

We have to announce a discovery or an invention perfected in Niagara County, that is destined to revolutionize the trade and commerce of the world; to give almost absolute security to life on the sea; and to practically annihilate time and space—in other words the practical application of the telegraph and telephone to moving vessels on the ocean, rendering certain the instantaneous communication between any ship or steamer, at any point of latitude or longitude with any port of the world.

THE INVENTOR.

The inventor, from whom we gather the information contained in this article, is Pierre Valcour, a Frenchman, 43 years of age. He was born in a small village in the *department du Rhone*, in France, of parents of the middle-class, and at the age of 17, entered the Polytechnic school of Paris, and was subsequently graduated with high honors. He adopted the profession of mechanical engineer, but not prospering in France he came to the United States, resolved to master International Law and practice in the Admiralty Courts at New York. His success was intermittent,—at times making large fees, at other times being compelled to live on his small income of 6,000 francs, derived from his father's estate. His occupation threw him into perpetual contact with all classes of commerce, ship owners and captains, the great trans-atlantic companies, the Chamber of Commerce, inventors, the Weather Bureau Service, the detective service, and other branches, making up Marine society, until he became intimately acquainted with, and had a passion for, all that relates to commerce and the sciences and arts governing its progress. M. Valcour, however, was a man of ease, and luxury as well, and up to forty remained a bachelor; and he might be frequently seen enjoying a dish of maccaroni at Moretti's on Fourteenth street, in New York, or lounging of an evening in the parlors of a fashionable up-town club. "Soon after meeting Madame Valcour," said the inventor to the writer, last Tuesday, "I began to take a more serious view of life. Our marriage happened about two years ago; but my French friends in New York made such demands upon my time that I concluded to leave the city, live on my income in a retired country house, and work out the invention you are now inspecting. But my wife, who was born in Copenhagen, would not consent until she had seen Niagara Falls. We made the visit, and while there learned that this house and these few acres could be reasonably rented, and here we are in Hartland."

THE INVENTION.

M. Valcour then took the writer to a large shed, which he said contained the principal apparatus for keeping up telephonic and telegraphic communication with a vessel going at the highest rate of speed in any weather, with the main shore. The entire machinery was encased in a cigar shaped metallic float thirty feet long. A longitudinal section through the middle of this shell, presents a perfect ellipse, the greatest diameter being six feet, or one fifth of its length. This shell is one-eighth of an inch in thickness, made of the finest gun barrel metal, presenting, when water tight, a perfectly smooth, glazed surface. Within this shell are a series of reels mounted on axles, which are seated in sockets perpetually oiled by a powdered lubricator of the nature of talc, steatite, or soap-stone. It is on these reels that were coiled over 5,500 miles of perfectly insulated composition wire, the fine wire being made under the highest possible tests, of the best material known to electricians. But the wire does not appear to be the important feature at all. "You know," said M. Valcour, "that one of the chief problems in laying the Atlantic cable was perfect insulation, and you are aware what a many-stranded cable it is, covered with adhesive substances, variously compounded. Of course then, I sought to fabricate a single wire, so insulated that the electric fluid, and sound itself, could not be impaired by immersions, and I have succeeded, and this part of the invention I shall disclose to no one. Nor shall I patent it, for the reason, that in making my specifications I shall be obliged to name the process and the materials—and this could be made public, for you have only to enclose twenty cents to the Patent Office, and they will forward you any patent." M. Valcour then said if the writer would like to see the apparatus working, he would have his portable boiler fired up and we could see the wire reeled off at twenty miles an hour. The writer assented, and while the machinery was being put in readiness by James Andersen, a Dane, M. Valcour introduced the writer to his wife, and a plentiful luncheon was enjoyed in their joint society. Madame Valcour is a beautiful blonde, strongly betraying her Norse origin, both in feature and accent, and is evidently deeply interested in her husband's invention. "*Qu'il étonnera le monde encore!*" She exclaimed, with rapture, as we repaired to the shed to renew the inspection. The engine was now in readiness; and a large reel was placed on a horizontal shaft and turned rapidly, the bearings being carefully oiled. M. Valcour then placed the insulated wire lead, ing from the metal shell over the engine reel fastening the end to it; so that as the reel in the shell fed out, it might wind up. The engine was started; the reel began to wind up while we noted the revolutions. Almost instantly the wire was being taken up at the rate of twenty miles an hour; and, to gratify the writer it was run up to thirty miles an hour, or twice the speed of ocean-going vessels. "Now," said the inventor, "you will note that when this wire is being paid out by the shell at sea, which is towed by the vessel, it will be put to no such violent strain or tension as here, when it is being literally wound up by machinery. Here everything is violence; there everything is mild."

As the operation continued there was no break or flaw. M. Valcour then explained the practical adaptation of this shell to navigation, which, as will be seen below, has already been demonstrated. The float or shell is so weighted in the distribution of the metal that it will always sit on the water, with its slight keel down, and float like a boat. It is towed to the stern, say of an outward bound steamer, and to a large ring-bolt in the bow of the shell a chain cable is made fast, and likewise the other end to the stern of the vessel. This chain cable is one hundred feet long, to enable the float to keep out of eddies formed in the wake of the vessel. There are also side chain-braces secured to side bolts in the shell and leading to the vessel.

From the telegraph and telephone station on board ship the, wire is led through a metallic pipe to the stern; it then enters a small perforation, carefully prepared at the bow of the shell, and enters the foremost reel in the shell. This wire going over the combination of curiously placed reels by varying sizes, is uninterrupted throughout its entire length—hundreds of miles more than enough to traverse the usual pathway of ocean-going steamers to Europe. The shore end of the wire is connected with companies' offices in New York; and when the vessel drops down to Sandy Hook the wire from the sternmost reel in the shell is connected there. The vessel starts out to sea; the wire begins to release itself. When two hundred miles have been accomplished, an automatic connection releases a leaden sinker, weighing five pounds, and this as the vessel goes on, finds its way to the bed of the ocean. At the point where the sinker is attached, the wire is much heavier—for a distance of two hundred feet. Thus at every two hundred miles—this shell, which is full of automatic and clock-work machinery releases a sinker, thus fixing a telegraph wire on the bed of the ocean. The object of the shell is simply this that the wire shall not be at the mercy of the rolling and pitching of the ship, so that no great strain shall fall either on the apparatus or the wire;—and as the shell is kept in its place by braces and the tow-chains, ample slack of wire is had between the reels in the shell and the operating instrument on board ship.

SUCCESS DEMONSTRATED.

"Yes," said M. Valcour, in reply to the writer, "success is demonstrated beyond a doubt." "My wife's cousin, Ernest Ballock, is master of a Danish ship which left New York on the 12th of December and connected with a station I established in Staten Island. He towed one of my shells out, and the wire and whole invention complete—all unknown to any one and not made public until I gave it to you to-day. Here is a letter which you see is in French—a copy; but here is the original in Danish." The writer extracts as follows:

QUARANTINE STATION.
New York, Dec. 26, 1879.

Mon cher Pierre:

* * * * * *

As you know when I left Staten Island all went well, and as we were in constant communication, until last night there is not much to tell—except this, that I gave the crew too much liquor without knowing its strength (I got it in Glasgow), to celebrate the great success, just as we sighted Sandy Hook; and could trust no one—not even my first mate, so I locked up the cabin and instruments and handled the ship with the pilot myself.

* * * * * *

We sailed in course S. S. E. pretty nearly all the time, averaging in the seven days, bound but 184 miles a day, running 1,288 miles. In returning to Sandy Hook I took a longer course making the run 1,356 miles. Thus we maintained telegraph and telephone communication in the heaviest weather over 2,644 miles.

Our little daily, written by my son, called the "Ocean Wave," I have sent to the Historical Society, as you desired. It contained on Dec. 23d, the London dispatch of the loss of the *Borussia*.

* * * * * *

THE GENIUS OF THE INVENTION.

The chief point about this invention is very simple—it is the *strength, small size, and absolute unimpaired conductivity of the wire for long distances when insulated and immersed in water.* This has been attained. The wire was made in Pittsburg, and has a core and envelope I am not permitted to describe. It may be said also, that there is an automatic repeater within the shell to use in case it were necessary for greater electrical force. Neither, "Kerite" wire, nor wire made by the American compound wire company can equal this thin thread of Valcour. Nor is there any difficulty in the mechanism, as every practical seaman will note. Mr. Valcour says that the only criticism he fears is in picking up the wire when returning from Europe. This will be done on the return voyage, when the vessel arrives a few miles from the first sinker. An ingenious *detachment* spring is operated by the electrical current so that the sinker releases the wire, and so the operation is continued, until it is reeled up on board again, for use in another voyage. This will keep the vessels to the well-known "Steam Lanes," or defined ocean routes, so often advocated in the New York *Herald*. The towing of the shell in no wise interferes with the steering of the vessel; but in a storm is an additional safe-guard as a jury rudder.

EXPENSE, INTERFERENCE AND EDISON.

M. Valcour says that the expense will be trivial compared with the advantages to be enjoyed, and would be little more than the cost of the wire, which he is prepared to furnish by contract at astonishingly low rates and also his shells. The query was made whether he anticipated trouble with Edison. He said hardly; that although this was an application of the telegraph and telephone, he did not see how he could be considered a poacher on the preserves of the great electrician. However, he would be glad to hear from Edison on the subject, and he thought he could give that inventor, an idea or two. M. Valcour has not as yet parted with any of his interest, although sought after from all directions where the success has been made known.

TELEPHONING 3,500 MILES.

Before the writer left he maintained perfect telephonic communication with M. Valcour for over half an hour through 3,500 miles of wire coiled in the reels in the shell.

THE EFFECTS OF THIS WONDERFUL INVENTION.

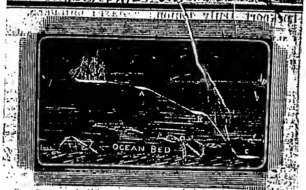
The results of this invention, almost immediate, cannot be overestimated. Among the first, M. Valcour proposes to establish a small printing establishment and issue a little daily sheet on every ocean steamer plying the seas. This right he proposes to become the owner of and issue his journal called the *Ocean Wave*, so that no traveler by the sea will remain for an hour ignorant of the world's doings. Private messages will be taken and sent. Friends can hear each other's voices from mid-ocean to shore, and shore to mid-ocean. Instantaneous news of disaster can be flashed to the seaport left—say New York—and as the point of latitude and longitude is told, and as the other companies know the exact position of their ships or steamers, a hundred succoring ships or steamers can be sent with relief; and as the tracks of commerce are now known and followed no serious disaster can occur. Other results, will be the constant money speculations that can go on by wire. Criminals afloat can be apprehended, the march of storms be made known; deaths telegraphed. The entire shipping department of the New York *Herald* will be revolutionized. Cargoes can be bought and sold in transit; contracts made; marine insurance effected—and thus will life become almost perfectly cosmopolitanized on every sea and shore.

M. VALCOUR'S ADDRESS.

M. Valcour's address is Pierre Valcour, Lockport, N. Y., and he is willing he says to answer pertinent enquiries.

118

LOCKPORT DAILY UNION FEB 3 1880



NOTE.—The Cut represents the Cunard Steamer Asia, bound to Liverpool. From the stern of the vessel to A, which is on the surface, is the chain cable towing A, the metallic shell in which is contained 3,000 miles of wire and the apparatus. B and C should have been smaller, as they are only sinkers, finally anchoring the wire on the bed of the ocean. On the return of the vessel she carries another apparatus, in all parts like this, and while keeping up communication with Liverpool, she winds up the wire laid from New York, as explained below. A permanent wire can be laid too superseding the cables now in use.

THE CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The number of messages passing over the lines of the Cuba Submarine Telegraph Company (Limited) during the month of January was 2,891, estimated to produce £3,200, against 2,687 messages, producing £3,043 in the corresponding month of last year. The traffic receipts for the month of November, estimated at £3,000, realised £3,110.

Eng'l Mech News Dec 1st 1881

The system of underground telegraph wires has been adopted in Philadelphia, and a company is busy digging trenches and laying tubes. A trench is dug in the middle of the street, three feet nine inches in depth. The bottom and sides of the trench are lined with concrete. The tubes, two inches in diameter, are then put in place, five in a row, and four rows, one above the other. A composition of pitch and slag is then poured in, until the pipes are covered, after which the top is cemented with concrete. The ditch is then filled in and the earth rammed down. It is calculated that the twenty tubes will accommodate from 1,000 to 1,500 wires. A man-hole is placed in each square, and the wires will be forced through after the tubes are all laid. The work is mostly done at night.

Scientific American, Aug 4th 1881

EXPERIMENTS WITH UNDERGROUND WIRES.

After a three months' test of their system of insulating telegraph and telephone wires underground, the National Subterranean Electric Company have applied for permission to introduce their system in Philadelphia. The company claim that when once introduced on their plan, telegraph, telephone, or other wires can be used in separate chambers, and that no disturbance of the pavement will be required for repairs or for additional wires. In the experiment referred to, in Camden, the telephone wires were, after three months' use apparently in as perfect condition as when first laid down. The plan embraces a system of terra-cotta cylindrical blocks, perforated lengthwise with several small holes, vitrified and lined with rubber. These blocks are laid end to end, cemented together, and form groups of pipes through which wires or cables are run. These pipes are laid in sections, at the end of each a sunken chamber affording workmen access to the pipes and wires for purposes of repairs or laying additional wires, which can be strung through the sections from chamber to chamber. The chambers are covered when not in use, and afford no obstruction to travel. The cost of the system is not given.

What is claimed as a cheap and durable system is under trial in Prospect Park, Brooklyn. The wires are strung in a trough of pine wood, into which is poured a mixture of pulverized glass, resin, and other ingredients made semi fluid by heat. In this compound, which becomes hard on cooling, the wires are hermetically sealed. It is claimed that the mixture has a very high insulating power, is durable, and sufficiently elastic to maintain its integrity under varying pressure. A bundle of wires of any length can thus be laid in sections without a break, and operated with a relatively small battery power, owing to the perfection of the insulation. The cost of the system is given at $1,500 a mile. The number of wires and the space between them are not given.

A more expensive and not altogether satisfactory system is used in London, where something like a hundred miles of underground lines have been laid. In this system the iron or earthen piping is in sections of 200 yards, separated by test and joint boxes. The cables are composed of 60 No. 18 copper wires insulated with gutta percha. The cost is given at about $7,000 a mile. The maintenance of perfect insulation is difficult, and when a fault occurs the whole cable has to be withdrawn and repaired.

Professor PERRY explained this action by the hydro-dynamical fact that the pressure is less at the centre of the mouth of the cup than at the edges.

Professor GUTHRIE said that he had tried a similar experiment with a funnel-shaped mouth and a glass cone, but failed. He surmised that perhaps the cohesion of the water for itself, as it formed a shell round the ball, might help to cause the success of the ball method.

Professor ADAMS pointed out that with the cup and ball there was less difference of head of water between the centre of the mouth and the edge where the water escaped than with the funnel.

Dr. STONE stated that he had been able recently to imitate many physiological sounds, such as the murmur of the heart, by means of constrictions in tubes through which water and air were flowing. His demonstrations were made before the Royal College of Physicians.

Dr. C. W. WRIGHT then read an important paper

ON A DETERMINATION OF CHEMICAL AFFINITY IN TERMS OF ELECTROMOTIVE FORCE.

After giving a history of the subject, he described his original experiments. These consisted in performing electrolysis of sulphuric acid, and measuring the heat evolved in the process and by recombustion of the materials. A voltameter with spade-shaped platinum electrodes soldered to stout copper wires, and sealed by a large plug of gutta percha, was employed for the electrolysis. An ordinary water calorimeter was used to measure the heat given off, as Bunsen's was found to contain sources of loss of heat. The strength of the current employed was varied from 6 Webers to $\frac{1}{10}$ Weber. The volume of gas produced was measured by Joule's plan. Radiation loss was corrected for by three methods. From an average of eighteen experiments the value of e, the electromotive force was found to be 1·5038 C.G.S., or volts. Taking the formula $J = \frac{e}{(H + h)\chi}$, where J is Joule's equivalent, H is the heat actually evolved, h the heat evolved by the recomposition, and χ a constant, to which Kohlrausch gives the value of ·000105, Dr. Wright finds that Joule's equivalent should be $4·196 \times$ by 10^7 instead of $4·20 \times 10^7$ as given to answer the formula. The author thinks that Joule's water-friction experiments gave the truest value of J, and that his electric heating experiments gave a result about $\frac{1}{2}$ per cent. too low, owing to the B.A. unit of resistance being about 2 per cent. too high, and other causes.

Electrician March 6 1880

THE DIRECT UNITED STATES CABLE COMPANY (LIMITED).

Report of the proceedings at the fifth ordinary general meeting of the Direct United States Cable Company (Limited), held at the City Terminus Hotel, Cannon-street, on Friday, 27th February, 1880, at twelve o'clock noon; JOHN PENDER, Esq., M.P., in the chair.

The notice convening the meeting was read.

The CHAIRMAN: Gentlemen, as you have had the report in your hands for some days, I presume you will take that as read. I should like in the first instance to make a few remarks as to the figures in the report, in order, if possible, to make it so clear that there may be no difficulty in discussing it on its merits. It will be seen from the Company's accounts that our revenue for the half year to 31st December last, after deducting rent of land lines and payment to Anglo Company, amounted to £120,445 8s. 6d.; and the working and other expenses, including debenture interest and income-tax, absorb £25,001 3s. 6d., leaving a balance of £95,444 5s. as the net profit of the half year, making, with £2,345 1s. 5d. brought from the previous half year, a total of £97,789 6s. 5d., which has been appropriated as follows:—Two interim dividends of five shillings each per share for the quarters ended the 30th September, and 31st December, 1879, together requiring £30,355, have been paid; an amount of £48,942 2s. 9d. has been added to the reserve fund (which is thereby increased to £150,000); the sums of £1,900 on Preliminary Liquidation and Arbitration Account, and £914 7s. 1d., the cost of removing spare cable have been written off, and the balance of £15,677 16s. 7d. is carried forward to the next half year. Our revenue in the past half year, as compared with that in the corresponding period of 1878, has increased by the sum of £30,501 12s. 10d. This satisfactory result is mainly owing to the revival of trade between this country and America. The working and other expenses show a balance of increase of £3,250, which is accounted for as follows:—Compromise of Colgate suit, including law and other charges incidental thereto, £2,560. I think it is right I should explain to you that this Colgate suit is the reversion of an old patent which was obtained in America, and a claim in respect of royalty upon the covering of copper wire with gutta percha. That patent existed in this country, but expired many years ago. The American patent in some way or other had been in existence at a later date, and curiously enough the inventor, or rather, the trustee of the inventor, took the question up and gained a decision in more courts than one in America. Therefore, that involved a compromise; but, fortunately for us, we got out of the matter by that compromise at a comparatively small expense. I believe that the trustee of the inventor in America has got a very large sum of money from land lines in America in virtue of that patent. Then there is the opening and furnishing new stations in America and building in Ireland, £830; extra printing and stationery, £410; maintenance and renewal of instruments, £360; debenture issue and miscellaneous, £720; making a total of £4,880. But, as against this increase there are many items of decrease, amounting to £1,630, leaving as net increase of expenditure £3,250. Omitting from these details the special expenditure re Colgate, it will be seen that the other items of increase were unavoidable, inasmuch as without the extra outlay it would have been impossible to earn the largely increased revenue. The above explanation of the increase in our expenditure, &c., having been given, no other item in the accounts appears to call for special remark [applause]. Now, gentlemen, I hope I have put before you very clearly the state of our finances, and I think I may congratulate the shareholders on their very satisfactory character. Therefore I need trouble you no further with these details. No doubt there are gentlemen in the room who may require to ask some questions on those accounts. If so, I shall be very glad to reply to any criticisms that may be made upon them. I may also congratulate you on the fact that since April last our cables have been working in every way satisfactorily, and the result has been the large return which your accounts show. I have no doubt that there are many gentlemen present who will be naturally anxious to know how we stand in relation to the new French cable [hear, hear]. It may be in your recollection that six months ago I gave you an outline of the French competing scheme. Since then the line has been completed, but I can scarcely say yet that it is open for general traffic. Messages have passed over the line, but at the present moment the telegraphing public know very little about it, and I suspect those who are immediately interested in the cable know a great deal more than it would be pleasant for them to communicate. So far they are very much in the position which I indicated—they are doing no good for themselves, but they are inflicting damage to a very considerable amount on telegraphy generally. I also stated six months ago, when these shares were at a premium in France, that in my opinion before twelve months were over they would be at fifty per cent. discount. I saw those gentlemen who formed the syndicate, for I went to Paris for the purpose of doing so, because I thought it was only right that those men, who must be ignorant of telegraphy generally, should be informed on the subject. I found one of them sitting at his desk with his pen in his hand, and I told him to make this note—that in twelve months, if I then returned to France, I should be able to sympathise with him on the loss of fifty per cent. of his property. To-day I can prove the truth of the prediction, for I now hold in my hand an official quotation from France, made only yesterday, which states that the shares have been sold at £11 each, which is close upon fifty per cent. discount. We may infer, therefore, gentlemen, that the cable manufacturers, the syndicate, and the French public generally, are in no way satisfied with their bargain. The contractors have pretty well exhausted England, as you who formed this Direct company know. For three years the shareholders got nothing out of this Direct company; and the syndicate lost £550,000. I have no doubt at all that if the new French cable were to fall into better hands, those better hands will probably by business-like arrangements be able to bring about the same result which has been brought about on our system; but then, gentlemen, it will be at a loss of about 50 per cent. on the original cost of the cable. As I have said they have exhausted England, I may say that they have pretty well exhausted France by this time also; and we are informed that they next propose to try Belgium, and, if that fails, Germany. But I should say that after the two attempts which have been made by the same parties, in which they have so signally failed, in carrying out the promises made in their prospectuses they will find out that other countries are not likely, particularly Germany, to engage in such a losing game. Schemes, such as the French cable scheme, are got up, as you are aware, by contractors and syndicates simply for the purpose of getting money upon the transaction, regardless of all consequences to telegraphy or to the investing public. Within a year they may get up a company, and within a year they may lay the cable, and hand it over to the Company; the public lose their money, the contractor probably puts something into his pocket, unless he has taken the amount of his contract in shares, and the result is that he goes elsewhere to find out another field for his enterprise. When telegraphic enterprise was first started, syndicates were a necessity, as it was almost impossible to get money from the general public; but now that telegraphy is established as a commercial necessity, and its real value ascertained, the public are not likely to subscribe for any enterprise unless they see a return commensurate with the risk. I have always held at public meetings of telegraph companies which I have had the honour of addressing that submarine telegraphy ought to pay from 8 to 10 per cent. dividend. I hold the same opinion now. It is a very curious fact, if you look at the telegraph companies generally, that the public estimate and value the telegraphic enterprises pretty much at that rate. No doubt in the early days of telegraphy 10 per cent. was necessary; but now that the public estimate the value of the telegraphs more accurately, and consider them more secure as a property, the returns are less. I may say that the telegraph returns upon the price which you can buy them at to-day give something like from 6 to 8 per cent. The amount of money at present invested in cables is about £25,000,000; the amount of reserve fund put aside by all the telegraph companies amounts to £1,630,000; but to replace the deep sea portions of these cables, an amount of £12,500,000 would be required, and until this amount is obtained it would not be wise in my opinion to consider submarine telegraphy in the sound position in which its friends would wish it to be placed. On this point I think it necessary to be very clear and distinct, so that there may be no misunderstanding between shareholders and directors. The Direct Company's cable has been laid nearly six years; for three years, as you are aware, it paid no dividend, and put aside no reserve. It has been nearly three years under the present direction, and in that time we have paid you a dividend of 5 per cent., and have accumulated an amount of £150,000 for reserve. Had the proper course been pursued from the beginning, and a proper reserve laid aside, we should have at the present time £300,000 as a reserve fund. The average life of a cable is said to be ten years, but as to this much depends upon the bed on which the cable is laid. I believe it would be difficult, if not impossible, to raise a cable from 2,000

116 A 118

fathoms after being ten years under water; still, it is quite possible that a deep sea cable might live for twenty, thirty, or forty years, or even longer so far as the insulated core is concerned, because in all our raisings of cables that have been in the sea for a very considerable time, we find that the gutta percha is almost indestructible as far as sea water is concerned. As that is the life and heart of a cable, if you could only get armour plating sufficiently strong to resist the action of the sea water a telegraph cable might live for a very long period. However, let us assume the life at ten years. The reserve necessary to replace the deep sea portion of our cable in that time would be £52,300 per annum, but if we raise the life to fifteen years we should require £32,300 per annum. I think, gentlemen, the safer principle to go upon is to put aside the larger sum, and when we exceed the ten years and our cable is still living, and in a profitable working state, then the Company can afford to pay a very considerably increased dividend, or probably it would be better to give bonuses. I submit, therefore, that the policy, not only of this Board, but the policy of all Boards of submarine telegraph companies, should be to accumulate a large reserve. There is another point I must touch upon, and that is the often expressed desire in certain quarters for reduced telegraph rates. Now, I think I have shown you that a reserve fund is a necessity to secure permanency of telegraph property, I think I can now show you that the reduction of rates from the commencement of telegraphy has been very striking indeed. When the telegraph was first established, the tariff across the Atlantic was £20 a message; it has gone down steadily, and now an average message costs 30s., in fact, a message can be sent across the Atlantic for 9s. When we reflect upon the ingenuity of the code and packing systems, we find that the amount of matter that can be transmitted at this low rate is almost beyond calculation. I may repeat what I have often stated at these meetings—if we had now an open system, instead of the code system, to deal with, for the matter which is passed over our lines we should realise the most sanguine anticipations entertained in the early days of telegraph property as to dividend. I remember myself, in the very early days of telegraphy, talking with Mr. Cyrus Field, and his saying that nothing less than 50 per cent. would satisfy him as a proper return for these telegraphic cables. That was a very sanguine view; but, if the open system had been continued to-day, it would have proved pretty much what he stated. But the ingenuity of the coding and packing system has reduced us, as I will show you, to a very low dividend indeed. It is the public who have really got all the benefit of the telegraph. If we take the capital of all submarine cable companies at the present moment, we find that the amount is over twenty-five millions sterling, and taking all the dividends that are earned upon these twenty-five millions, we find it to come out at only 4-1/8th per cent. It would therefore, I hold, be unsound policy both in the interests of shareholders and of the telegraphing public, to talk of reducing rates at the present moment. We must remember that a submarine cable can only carry a certain number of words, and, taking the working time of a cable, it requires 2s. a word to give but a very moderate return upon the invested capital in these Atlantic systems. So far as the Atlantic tariff is concerned, any reduction leading to an increase of messages would not lead to a larger return in money, because at a low rate it would be impossible for a cable to carry the number of words required to make it pay. To carry messages at a low rate additional cables would be required, which, of course, involves additional outlay of capital and reduction of dividends. The present tariffs are in no way checking telegraphy, as we may plainly see, if we take last year as an evidence, for there is a large increase in the return of telegraphs generally. As I have often said, telegraphy is the best barometer we have of trade. With good trade the returns rise rapidly. With bad trade they become correspondingly depressed. The increase in the telegraph companies' returns is one evidence, which I think we have all good reason to congratulate ourselves upon, at the present moment, that not only in America, but also in India, and, in fact, throughout the world, trade is getting into a brighter and sounder position; and that is an evidence which I believe will brighten many a home [hear, hear]. We must deal in this question of telegraph tariffs with averages, and I hold that the rates we are now charging are a fair average, and must be maintained until the reserves I have indicated are secured. Having now shown you by figures that it is desirable to largely increase the reserves, and that it is undesirable and impolitic to reduce tariffs, I will just say one word as to the position which submarine telegraphy occupies at the present moment, and what it has had to contend with. Telegraphy has had little or no support from governments. Governments have never hesitated to grant concessions to anybody who might apply for them, encouraging, as they say, competition. They even go so far as to prevent any cable landing upon their shores (I am speaking of England, France, and the United States) who hold any concession or special privileges, while they do this, throwing every obstacle in their power in the way of submarine telegraphy (and I should be glad to have an opportunity of proving this to the governments) becoming a remunerative enterprise, although they admit it has become a great necessity both for imperial and commercial interests. But instead of dealing with it on the same principle that they deal with their own telegraph systems, which in every country is a vast and close monopoly, they are strict to a degree in upholding their own monopoly, but they lose no opportunity of destroying what they are pleased to term the monopoly of submarine telegraphy. I hope the governments will see these things in their proper light, and that they will consider well when concessions are asked for, whether they are sought in the interests of the public generally, or are meant to enrich speculative contractors, to the destruction of sound telegraph enterprise. Telegraphy does not admit of undue competition. It has had to be established at enormous cost, and is of a very speculative and uncertain nature. Until science has done more than it has yet done to render cables permanent, the greatest caution ought to be observed on the part of governments, and I may say also on the part of individuals, in order not to destroy the fabric which has done so much, not only to promote commercial interests, but civilisation to a degree more rapid than anything has yet been known in this or any other time in the history of the world [applause]. Gentlemen, I have felt it necessary to-day to give you a few details, which I dare say will be interesting to you, as showing the position in which telegraphy is at the present moment. I believe that the value and assistance of telegraphy is only beginning to be felt at the present moment. Great as the benefits are, which it has conferred upon mankind, there are still greater benefits to be conferred by it; and I think that all those who have been interested in telegraph enterprise from the beginning may congratulate themselves upon the fact that they not only have had a moderate dividend, but they also have the satisfaction of knowing that their property is an increasing property, and that they have conferred an enormous benefit upon the commercial interest and the public generally [hear, hear, and applause]. Gentlemen, having troubled you with these few remarks, I beg to move the following resolution:—"That the report of the directors, dated 13th February, 1880, together with the statement of accounts to the 31st December, 1879, annexed thereto, be and the same are hereby received and adopted."

Mr. W. Ford: I beg to second the resolution.

Replying to Mr. Jackson and Mr. Newton,

The Chairman said: Mr. Jackson has entirely endorsed the policy of the Board. He has asked the Board to stand on that policy; but he has stated that so far as our cable is concerned we are in a very uncertain and very unsatisfactory position. I do not agree with Mr. Jackson in that respect, because our arrangements with the Anglo-American Company are of a very satisfactory nature. We should have ample time to repair our cable if it were to break, without suffering in any way in our dividends. At the same time, were it to break in deep water there is no doubt at all that we should require to find a new cable. Our cable is still young and healthy, and I think it is in that position which, if it were to break to-morrow, as we have got a very good nest egg to begin with, and plenty of time to repair it, and sufficient shallow water that would limit the amount required for the cable to a very small proportion indeed. I take, therefore, a much livelier and brighter view of our position so far as our own cable company is concerned than Mr. Jackson does. We are, certainly, the junior partner; but we are supported by all the means, and all the powers of the Anglo-Company with regard to help in case of need. I do not go in for monopoly, I have always been opposed to monopoly. When we extricated this Company from its troubles we were most decided in that view; we felt that to be absorbed by the Anglo-Company was simply giving place for another cable to spring up. As long as I have the honour of being chairman of this Company, it will never be considered a monopoly, as I am opposed to monopolies altogether. I say that submarine telegraphy is a matter of enterprise, and is not good ground to be poached upon by any other class of property. It is an uncertain property, as we all know, and that man who came forward to induce other people to find money to lay cables where they could get a better security for half the price at the same moment shows that the public are still what I will call very gullible indeed, but I hope that every day is opening their eyes in that respect. With reference to Mr. Newton's question, I was going to make the reply which Lord Monck did, which I think was a very sound and proper reply. Only last night in the House of Commons a question was put to one of the ministers, and the minister's reply was "During negotiations it would not be to the public interest that anything should be said about it." During the present stage of negotiations between the French and English companies, I think the less said about it the better [hear, hear]. All I can say is, that they are doing nothing, and with a large capital lying unemployed, every day is strengthening our position and weakening theirs. You may depend upon it, when it comes to close quarters, if a bargain is ever made, that the interests of the shareholders of this Company will be fairly protected.

The resolution was then put and carried unanimously.

Mr. Jackson: I beg to move that the best thanks of this meeting be accorded to our worthy chairman for the way in which he has presided over the affairs of this Company. He is a gentleman who is not only A 1 as a telegraph director, but is so devoted to our interest, that I am sure we shall not hesitate for a moment to express the gratification we feel in having the opportunity once more of expressing our acknowledgments for the services of himself and his Board.

The motion having been seconded, was put by Mr. Jackson to the meeting, and carried by acclamation.

The Chairman: Gentlemen, we are very much obliged to you for this renewed mark of your confidence. I am sure there is nothing more gratifying to my co-directors and myself than to find that our shareholders are satisfied. I think that, looking to the affairs of this Company altogether, we have reason to congratulate one another at the respectable position in which we find ourselves to-day.

The proceedings then terminated.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).

The sixteenth ordinary general meeting of shareholders of the above company was held on the 2nd inst. at the City Terminus Hotel, Sir Daniel Gooch, Bart., M.P., presiding.

The Secretary (Mr. W. Shuter) read the notice convening the meeting, and subsequently the minutes of the last ordinary and half-yearly meetings, which were approved by the present meeting, and signed as correct by the chairman. The report, which appeared in *The Electrician* last week, was taken as read.

The Chairman, in moving the adoption of the report and accounts, and a dividend (tax free) of £1 16s. per share (making with the interim dividend 20 per cent. for the past year) said that he need not detain them very long, because the affairs of the Company were set out so fully in the report, which, no doubt, they had all read. During the past year they had manufactured 6,917 miles of cable. The result in money was that they showed a net profit during the year of £98,988, after deducting the interest charged on their debentures. They brought forward from the previous year an amount of £59,353, making together £158,341 to dispose of. Out of that they gave an interim dividend of 5 per cent. in July last, which absorbed £22,410, and now the directors proposed to distribute a dividend of 15 per cent. for the past half year, which would require £67,230, and leave to be carried forward £68,701. That he thought was a very satisfactory statement of their financial working in the past year. The work done had been the duplication of the Australian cable, which they began very early in the year, but the completion of it was postponed in consequence of the necessity which occurred for the carrying out of the contract for the Cape cable, and the Australian Governments were good enough to consent to the postponement of the completion of their cable, so that it might be used for the completion of the Cape cable. They did not complete the Australian cable, therefore, till the beginning of the current year. With regard to the Cape cable, they laid that cable of 3,845 miles during the year, and it was successfully laid. Unfortunately, a break had taken place close to the shore of Mozambique, and when it happened there was no ship nearer than Aden to repair it. They had, however, that day received information that the ship had arrived on the ground, and no doubt in a day or two that breakage would be put right. It was a very bad bit of ground where it was broken, and some steps must be taken by the Cape Cable Company to see if they could find a better piece of ground. They started a ship on Saturday with 555 miles of cable to lay a line between a point near Manilla, in the island of Luzon and Hong Kong, and that work would be completed in the month of May. That was for the Eastern Telegraph Company. They had carried out a contract for the German-Norwegian Telegraph Company to make and lay a cable between Arendal in Norway, and Hoyer, on the coast of Schleswig. That operation was completed in August, and the length of cable was 256 miles. Last December they entered into a contract with the Government of New Zealand to lay a cable of 120 miles in that colony, and they had heard that day that the cable was laid, and that the ship was on her return home. The total length of cable manufactured in the year was, as he had said already, 6,917 miles, and they were, he thought, indebted to the officers and others who had been engaged in laying these cables for the care and ability with which they had completed their work. It was a very large extent of cable to lay, and they had had no misfortune to report. The accounts were set out in full detail, and, therefore, he did not think it necessary to refer to them further, but he should be very glad to give any explanation which might be required relating to them. They hoped that the present prosperity of the Company would continue; perhaps it might not be quite so great as it had been hitherto, but, at any rate, as far as the directors were concerned, they would do their best to carry on the Company's work satisfactorily. He concluded by moving the resolution.

Mr. Philip Rawson seconded the motion.

Mr. William Abbott thought that every one would endorse the chairman's remarks about the shareholders' obligations to the officers of the Company for the skill and ability which they had displayed in carrying out the work of the past year. He was in the habit of asking the Chairman many questions at the meetings of the Company, but he was also in the habit of receiving very scant replies. He had no doubt that both the chairman and he had the same end in view—the welfare of the Company—and that no undue inflation might be stimulated in the minds of the shareholders as to what might take place in future, he had made a small calculation, and found they had laid 6,917 miles, and that the net profit amounted to exactly £15 per mile. Considering the risks they ran in cable laying, he did not think their customers could make any complaint at the amount of net profit made by the Company on the works they had carried out. He should be glad if the chairman would inform them whether the distribution of dividend, which was very satisfactory to him, though it might have been very much larger, was limited to the usual 20 per cent. on account of the fact that they had securities to the amount of £343,365. He presumed that they had to render a considerable amount of assistance to the Cape company, and also to the other companies for whom they had done work, and that when those securities were in a liquid state the profit would be fairly divisible among the proprietors. They did not live for posterity—posterity had done nothing for them, and, therefore, it was desirable that the shareholders should see a little of the return in their life time, and not wait for all their reward in the next world.

The Chairman said Mr. Abbott was wrong in supposing that the Company had laid 6,917 miles of cable during the year; they had constructed that amount of cable, but the whole was not laid. As he had said in his opening remarks, the Australian cable was not laid till the beginning of the present year, and the accounts connected with that work did not come into the accounts under consideration. As he had told the shareholders many times, the success of the Company hitherto had been owing to their having large funds in hand. Without large funds in hand they could not have undertaken the Cape cable. It was very well known that the Telegraph Construction Company had to take practically two-thirds of the capital of the Cape Cable company upon its own hands, the Eastern Company taking the other third; but if they had not had those large available sums in hand they could not have undertaken the Cape cable. Therefore, although it looked a large sum in hand, yet their success depended on it. He was as deeply interested as anyone in having a large dividend, but still he looked to the prosperity of the concern, not for one year, but as a permanent investment for their capital, and he was quite sure that the course they had hitherto taken was a wise one. He did not think anyone could complain of 20 per cent.; he only wished he had that rate or half of it from other companies he was interested in. He hoped the shareholders would not inquire too closely into the matter referred to by Mr. Abbott, but that they would trust the directors, who had hitherto not deceived them. He thought that the accounts placed before them showed pretty generally the state of the Company financially. He then put the motion, and it was carried unanimously. He next moved the re-election of Lord Alfred Paget to his seat at the Board.

Admiral Sir George H. Richards, C.B., F.R.S., the managing director, seconded the motion, and it was carried unanimously, as was also a further resolution, proposed and seconded by the same gentlemen, for the re-election of Mr. George W. Campbell.

On the motion of Mr. W. Abbott, Mr. John Gano was re-elected an auditor of the Company, and Mr. James Glegg (of the firm of Quilter, Ball, and Co.) was elected the other auditor, to fill the vacancy caused by the death of Mr. John Ball, who, the chairman stated, had served the Company for many years, and paid great attention to their affairs. Mr. Glegg had been a partner of Mr. Ball's, and had lately assisted in the audit.

Mr. William Ford said that notwithstanding that the directors had thought it prudent only to declare the normal dividend of 20 per cent., and notwithstanding that they had thought it prudent not to supplement it by a bonus of 20 per cent., notwithstanding, too, that they had thought it expedient to carry forward £68,000 odd, he still thought, in spite of these shortcomings on their part, that they were deserving of a hearty vote of thanks. He hoped next year that they would have a larger dividend; a bonus, and that they would carry forward more.

Mr. Abbott, in seconding the motion, thanked the chairman for the information he had given him. It was true it was not much, but it was all he required.

The resolution was carried unanimously.

The Chairman thanked them for the renewed vote of confidence which they had passed. He could assure them that the interests of the Company had the deep thought and attention of the directors, and he hoped that they would meet under such pleasant circumstances for many years to come.

Mr. Ford then said that the shareholders would concur in the remarks of the chairman as to the services of the officers of the Company's ships who had been engaged in the various expeditions the results of which had been so successful. He was sure that those shareholders who were acquainted, as he was, with the great difficulties of the various expeditions would appreciate as fully as he did how much they owed of their prosperity to the energy and skill of those officers. He was extremely glad to hear them mentioned. He was sure that the shareholders would concur in passing a vote of thanks to the various officers and the staff of the Company.

Mr. Hancock expressed his pleasure in seconding the resolution. He had known some of the men referred to for 20 or 25 years, and he was sure that the great success of the Company had been due as much to the great care, experience, and skill of the officers as to the straightforward and honourable conduct of the directors.

The Chairman put the motion, and it was carried unanimously, and the proceedings then terminated.

MEDITERRANEAN EXTENSION TELEGRAPH COMPANY (LIMITED).

The forty-fifth ordinary general meeting of the shareholders of this Company was held at the City Terminus Hotel, Cannon-street, on the 3rd inst., under the presidency of Sir James Carmichael, Bart., chairman.

The Secretary (Mr. E. Tombs) read the advertisement convening the meeting, and the report of the directors was taken as read. It stated that the last half-yearly balance sheet of the Company showed a slight improvement over that of the previous half year. The cables were in good condition. They recommended payment of the usual dividend at the rate of [illegible] per cent. per annum, less income-tax, on the Preference Stock, and of a dividend at the rate of 3 per cent. per annum, free of income-tax, on the Ordinary Stock of the Company, on and after the 10th March, leaving a balance of £48 to be carried to the reserve fund. The revenue account showed that the receipts from messages during the half year ending the 31st of December last had been £2,281, and the amount due from the Government under the guarantee was £3,600.

The Chairman, in moving the adoption of the report and accounts, expressed great regret at the delay which had occurred in holding the meeting, which was usually held in February, and, as they were aware, the dividend was usually paid on the 1st of March. The delay had not arisen from any *laches* on the part of any of the officers or directors of the Company; but, unfortunately, the official auditor of the Treasury had demurred to the claim which the Company had made for payment of the guarantee—at least, they demurred to a portion of it. They thought that they were entitled to it, and the matter was still under the consideration of the Treasury. They had endeavoured to get this settled before the meeting of the shareholders, but as that seemed to be impossible they thought it better to leave the matter for the discussion of the Treasury, and he hoped that at the next meeting they would be able to make a favourable report to the shareholders on the subject. Those were the only remarks he had to make on the report and balance-sheet, but he should be happy to answer any question or give any information which might be required.

Mr. Harris having seconded the motion,

Mr. C. Robinson thought they ought to have some little explanation as regarded the different matters which were going forward with respect to the Company—for their prospects for the future appeared to be no brighter than they were at present. When they found the Government objecting to pay what the Board considered the Company ought to receive, the shareholders ought to ask the question in what position the Government stood towards them in respect to the guarantee, and, further, whether the amount they objected to pay the Company was a sum which they could legitimately claim back from them or not. Their solicitor was present, and he might tell them whether it was better to meet the dispute by an amicable arrangement, or whether they should insist on their rights. He thought they had very much truckled to the Government as to this matter. The Treasury were imposing very onerous exactions on them, and they seemed to dictate to the Board what they should do and what they should not do. He had several times made remonstrances with the Government, but they had not had the effect on their interests he could wish. They must look to themselves and not to the Government. The diminution of their expenses was considerable, and their cables were in perfect order. He thought a remonstrance from the shareholders would convince the Government that they must deal more liberally towards the Company. The Company had been in existence many years, and it was a disgrace to the Government that they should ever have sanctioned a competing line. Instead of promoting the interests of the Company, they promoted the interests of a company which was diametrically opposed to it. He knew that many of the messages which the Government sent did not come to the Company, although it would be thought that, as the Government had to pay the Company a guarantee, they would send all the messages they could through the Company, so as to reduce the liability they were under to the Company. This question had been brought before them lately, and he understood that they had no more messages. At one time, however, they received scarcely any of the Government messages. He thought the directors would be assisted very much by a large attendance of the shareholders at their meetings, and that some remonstrance should be made by the shareholders to the Government. Seeing the difficulty they now had in obtaining messages from the Government, when the guarantee expired they would receive no messages from

that quarter. At present the shareholders seemed to think that because they received this interest each half year it was to last for ever, and, therefore, they took no heed of the position of the Company.

The CHAIRMAN thought the last part of Mr. Robinson's remarks almost answered the first, for the Government had a right to terminate the agreement. It had nearly four years to run. If they could end the guarantee it was surely not their interest to quarrel with their paymasters. They must do all they could to carry on their business in an amicable manner. He had never found the Government hard taskmasters. They had paid them he thought very fairly and liberally. They had now a question open as to which he entirely differed from them. It was a question open to discussion, though he thought it was a hard matter to press on the Company, but he hoped they would do all they could to carry their point. He certainly would not advocate taking legal proceedings against the Government. He thought the better way would be to leave the matter in the hands of the Board to negotiate. The present Government was not answerable for the competing line to which Mr. Robinson had referred, and which was, unfortunately, inimical to this Company.

Mr. CAMPBELL (the solicitor of the Company) thought the time had not arrived for entering into any legal discussion on the subject, and he hoped that an amicable arrangement would be made. Of course, if it could not be, legal proceedings must be taken, but he really hoped that that would not be necessary.

The CHAIRMAN said they must remember that legal proceedings were very expensive operations.

Mr. ROBINSON replied that he did not advocate legal proceedings, but suggested that as Mr. Campbell was present he might tell them whether the Government had a legal right to make the deduction in question or not.

Mr. CAMPBELL said they believed that the Government had not.

Mr. ROBINSON observed that there was another point in the Articles of Association which had, he thought, missed their notice. The only prospect of the Company becoming a valuable one to the present shareholders, or to their successors, was for them to endeavour to grasp some other line, or to make an arrangement with some other company, and at present he believed they had hardly any power to make arrangements or contracts with any company or government to make or lay any lines of telegraphic communication whatever.

The CHAIRMAN thought that Mr. Robinson was quite right.

Mr. ROBINSON held that they should have the power to grasp anything upon that, and get the consequent advantage without delay. [illegible] might be put before them, and get the [illegible] to be provided in their articles. He thought the power should be [illegible].

The CHAIRMAN thought that was a very valuable suggestion, and he would be most happy, if the shareholders generally approved of it, to carry it out by suggesting a clause to be drafted [illegible] Mr. Campbell to carry it out [illegible] the Articles of Association. That could be done by two specials, if it [illegible] the wish of the shareholders. He thought it might be very advantageous to have such a clause in their articles.

The Hon. A. CONSONBY observed that they had often discussed the [illegible] but they thought the time had not quite come. However, [illegible] at the Board, it seemed to him that it would be quite feasible, and at their next general meeting, six months hence, they could make the meeting special, [illegible] the purpose of considering the question, and then call another meeting to confirm it.

Mr. ROBINSON remarked that there was an old saying, that if a thing [illegible] worth doing, it was worth doing at once.

The Hon. A. CONSONBY thought it would do if the subject were [illegible] at their next meeting.

Mr. CAMPBELL thought it might be left in this way: That if anything occurred which was likely to turn out well for the Company they could call a meeting, but if not they would make the next ordinary meeting special for the purpose. It was simply a question of saving money and time.

The CHAIRMAN said he had always regretted the power referred to was not in the Articles of Association originally, but nothing had been before them to necessitate taking the powers. Though he considered it was a very valuable power, he thought it would, perhaps, be better to leave the matter as suggested by Mr. Campbell.

Mr. ROBINSON acquiesced, and the report was then unanimously adopted.

The CHAIRMAN then moved the payment of the dividends referred to in the report.

Mr. DELFORCE seconded the amendment. He said that the amount available for dividend was £3,000, and on the other side they had £3,600 owing to them.

The CHAIRMAN said that the amount was owing by the Government, and was available for the dividend.

The SECRETARY stated that by various conventions with the Italian Government three months were given to them in which to close their accounts. This amount was available for dividend.

Mr. DELFORCE said he thought it might, perhaps, be the sum in dispute.

The CHAIRMAN replied that he was glad to say that the sum in dispute was much smaller than that. The motion was then carried unanimously.

Mr. ROBINSON moved a vote of thanks to the chairman and directors. [illegible] know the difficulties they had to deal with at the present moment, but [illegible] had no doubt that with the assistance of Mr. Campbell they would convince the Government that their claim on the Company could not be legitimately held. It was far better to close with the Government amicably than throw down the cudgels. They knew that it was a very difficult thing [illegible] a case against a Government. He thought that the suggestion of Mr. Campbell was a very good one.

Mr. LLOYD seconded the motion, and it was carried unanimously.

The CHAIRMAN, in returning thanks, said they would use their best endeavours to obtain what they thought they had a right to, and if they failed it would not be from any fault of theirs.

ADDRESSES.

Scientif. Amer.

ATLANTIC CABLES.

WHEN the first Atlantic cable was laid in 1858, each step in the operations was carefully reported in the daily press, and eagerly perused, owing to the novelty of the work and the intense interest it had aroused in the public mind. In the same way, though perhaps to a less extent, the operations of 1865 and 1866 were made public. In 1869 the cable laid between Brest and St. Pierre, known for some time as the French Atlantic, caused less interest. The cables of 1873 and 1874 were but briefly recorded, and the cables laid last year and this year have scarcely been noticed at all. This is partly due to the rivalry existing between the two telegraph companies, as well as between the firms who have made and laid the cables. Very little information is to be obtained on the subject from the principal persons concerned in the work, who, it would appear, wish to have as little made public as possible for fear of their adversaries gaining some advantage by it. This appears to us excessively childish, for any persons having sufficient interest in gaining particulars of either work, to be willing to incur a small expense and trouble, might easily obtain all the information he desired concerning the cables and operations. The rival parties themselves are not likely, therefore, to have any difficulty in knowing all that occurs in the enemy's camp, and it is only the public, and those who take an interest in the subject generally from a technical and scientific point of view, who are deprived of the information as to what is being done in this branch of engineering. There may be some slight advantage to contractors in thus keeping all experience and information as much as possible to themselves, but we doubt very much whether this exclusion of all, except those who are actually employed on the work, from any information as to the progress that is being made, is beneficial or will tend toward the advancement of telegraphic engineering generally. Improvements and new ideas do not always come from rich, conservative, and exclusive bodies or corporations, and unless what may be termed outsiders hear a little of what is on, it is unlikely that they will turn their attention to improvements.

That an improvement on the type of cable employed on the Atlantic in 1865 and 1866, and which is known among engineers as "Atlantic type," is required is proved by the fact that these cables had only lives of about 8½ years, and if cables will only last that time, even 10 per cent. dividends will not pay for them, whereas most cables at present only pay about 6 or 7 per cent.

The type we allude to consists in ten homogeneous iron wires, each separately surrounded with strands of Manila hemp, as the mechanical structure round the jute covered core. This type of cable when new is, of course, excellent for the process of laying. It has a low specific gravity and great friction from the roughness of the Manila hemp, and can consequently be laid with a given amount of slack with a very small strain during the operation of paying out. But as regards its durability it has little to recommend it. The wires being separated allow insects easily to enter. The hemp rots and the iron rusts away. The 1873 and 1874 cables had a little hemp and pitch and silica laid on round the whole, and have thus no additional protection, but the coating was meager.

The cable laid by Messrs. Siemens last year, we believe, consists of homogeneous iron wires touching one another, thus returning to what has been known as the Mediterranean type of cable, the iron being protected from rust by two coatings of yarn, pitch, and silica round the whole cable.

The cable laid this year by the Telegraph Construction Company has ten homogeneous iron wires, each covered with a thick coating of preservative compound called Clifford's compound, the composition of which is kept secret, and these are each separately further covered with tape. Between each wire a strand of hemp is placed. The whole cable thus formed has two layers of tape and pitch compound outside all. The mode of combining hemp and iron alternately round the core has been before largely adopted by the Telegraph Construction Company, and was first, we believe, employed on the cable between Sydney and New Zealand. We do not know what advantages are claimed for this plan, but it would appear to us to be principally a mode of saving first cost by substituting hemp for iron at the expense of durability. It does not seem possible that the hemp can take any strain properly with the iron, and when the cable gets old, we should think the hemp would not keep the wires in place when the cable is being strained or bent about in repairs so well as hemp round each wire. It is cheap, and that is all that can be said for it. The strong outer coating of tape and pitch no doubt keeps the wires in place when the cable is new, but we should look to what will be the state of the cable when this outside coating of hemp is gone. When the hemp has perished considerably it seems clear that the wires, with wide spaces between them like a bird cage, will not in the least fulfil the conditions of a wire rope, and we shall be very much astonished if after a few years of experience at repairing, this type of cable, with alternate wire and hemp, is not abandoned as a mistake. The attempt to preserve each wire with a compound, whatever it may be, is a step in the right direction. Gutta percha applied in the ordinary way round wires for protection was proposed and patented by Mr. Samuel Statham in 1857. We do not know what Clifford's compound is, but we doubt whether it is better than gutta percha, though perhaps much cheaper.

As regards the process of paying out there was one novelty in the Siemens expedition which we will describe. It is necessary, in order to distribute the slack of a cable uniformly or in such places as the engineer may decide on, to know at every half hour the exact position of the ship over the ground. To do this by observations even in fine weather is only possible once every twenty-four hours, and when the sky is overcast not even then. Dead reckoning is not to be trusted on account of currents. The following plan was adopted therefore, and forms one of the latest novelties in cable laying: a steel pianoforte wire was paid out throughout all the deep water passage with sufficient tension to insure its being laid without any slack, and thus the distance actually run was measured and known at every minute. The wire was, we believe, in 50 mile lengths on drums, and the lengths were rapidly joined by a hook joint.

In paying out the Anglo-American cable this year two ships were employed, the Scotia and Seine, and when the Scotia had nearly finished paying out her length, the cable was made fast to a buoy at some fathoms from the end, the stray quantity being coiled into a lifeboat, and the end thus handed to the bows of the Seine. We believe that in laying the Siemens cable last year there was a similar change from the Faraday to the Pouyer-Quertier.

It seems a pity that these operations are not published in detail, as they both no doubt reflect credit on those who have conducted them, and would be of great interest to all who follow up the important question of Atlantic telegraphy.

The laying of the Siemens cable, we believe, was under the superintendence of Mr. Loeffler, assisted by Mr. Brittle, Mr. Jacob being the chief electrician. The cable laid this year by the Telegraph Construction Company was under the charge of Captain Halpin, assisted by Mr. London, Mr. Laws being the chief electrician. Captains Cato and Manning commanded the two ships.—*Engineering.*

120 Electrician July 31. 1880

NEW SUBMARINE CABLES.

Electrician July 31/880 27

The India Rubber, Gutta Percha, and Telegraph Works Company have contracted to lay a cable between Marseilles and Algiers for the French Government during the present year. This will make the third cable the above firm will have made for the French Government for this route. The cable will be similar in pattern to that laid last year, the sheathing of the deep sea being 15 No. 13 homogeneous iron wires, with two tapes and compound. The length will be 500 miles of deep sea, 9 miles of intermediate and 16 miles of shore end, making a total of 525 miles, or 35 miles longer than the cable of last year. The steam ship Dacia belonging to the company is having water ballast tanks placed in her below her cable tanks. She will be employed in laying the Algiers cable. The operation of laying the cable will be conducted under the superintendence of Mr. R. K. Gray, the engineer of the company. The expedition will leave about the middle of September. A staff of French Government engineers test the cable every day at the works.

The same company are making the following cables for the Canadian Government:—Island of Anticosti to Griffins Cove, 2 miles shore end and 42 miles main cable—total, 44 miles. Prince Edward Island to the Magdalen Islands 4 miles shore end, 47 miles of main cable—total, 51 miles. Grosse Island to Bird Rocks, 4 miles shore and 15 miles main cable—total, 19 miles. Island of Grand Manin to Mainland (Maine) shore end 2 miles, main cable 9 miles—total, 11 miles, making a total of 12 miles of shore end and 113 miles of main cable.

These cables will be laid from the Dominion screw steamer Newfield, Captain Guilford. This steamer, belonging to the Dominion of Canada Government, is employed on the lighthouse and buoyage service in a similar capacity to our Trinity buoy boats. She will, however, be employed also to repair and maintain the cables, and for this purpose is being fitted at Silvertown with two iron tanks to receive the cable, and with bow and stern sheaves, with a machine for picking up and paying out, the one machine being constructed so as to perform both duties. Mr. F. N. Gisborne, C.E., has charge of the testing and inspection of the cable and fitting of the ship on the part of the Canadian Government.

N. Y. Mining Press Aug 21 '80

PROPOSED OCEAN TELEPHONE.—A Cincinnati company, says the *Iron Age*, is negotiating with the cable companies for the lease of a line for eight days for the purpose of testing experiments for telephonic communication with Europe. It is believed that the new French line will be secured. The arrangements, it is thought, will be completed in a few days. The process upon which the proposed work is to be done is based upon the Orangbough invention of 1868 and the recent Klemm patents. The tests will be made from New York city. Only the combination of the two systems mentioned will be tested, to the exclusion of the Bell, the Edison or any of the instruments now in active use, as the new company claim that they are actually infringing.

THE SS. Dacia, belonging to the India-rubber, Gutta-percha, and Telegraph Works Company, is now in the Mediterranean, employed in laying a third cable for the French Government between Marseilles and Algiers. The ship carries two electric lights, the current being supplied by two Gramme machines, worked by two separate engines. These lights light the deck for paying out, picking up, and sounding. Regnier lamps are carried for lighting the tanks. A sounding wire apparatus, with improved self-adjusting brake, is fixed permanently at the taffrail, on the starboard side, the cable stern sheave being on the port side. The machine is driven by a small engine fixed close to it, and connected by driving wheels with vulcanised india-rubber tires. The ship carries a buoy containing tanks filled with gas and carrying a lamp. Electric signals are fitted from bow, stern, and bridge to the engine room and helm, and there is a system of electric bells between all the cabins, chart rooms, deck-houses and saloon, to the stewards' pantry. 27 Engineering Oct 1 1880

Electrician Oct 2 1880

27 THE ELECTRICAL MACHINE IN TELEGRAPHY.—The state of the atmosphere it is well known has a very great effect on the conditions for the electrification of the ink by the "Mouse Mill," in the Thomson recorder, and at most stations where it is used this is more or less felt. At Porthcurnow, the Eastern Company's station in England, where the damp fogs come up from the Atlantic, and saturate everything, causing the electricity to disperse, instead of being concentrated to the ink well, the trouble is sometimes very great. A lamp burning near is not effective. An electrical machine has been tried, a wire from the collector brought to the plate leading to the ink well, and it was found that a good and constant supply can be obtained, which causes the ink to flow well. Of course it necessitates labour to turn the machine, but this is compensated for by the fact that if the mirror were used this would also entail a writer, so that a greater number is not employed, and it does not generally last more than an hour or so.

THE MARSEILLE-BONA CABLE.—*L'Electricité* observes that, although the new cable between France and Algeria is termed "the third cable," there are already three cables, in tolerably good condition, uniting these countries. Of these two, between Marseille and Algiers, belong to France; the first cable laid, that between Marseille and Bona, belongs to England, and is exclusively reserved for the transmission of despatches between Great Britain and Malta, Egypt, or India. Originally, this cable was used only for messages between France and Algeria. Electrician. Oct-9 1880

THE THIRD MARSEILLE-ALGIERS CABLE.—It appears that this cable has been laid between the two others; and *l'Electricité* urges that this position is an inconvenient one, and likely to lead to accident. On the occasion of the laying of the second cable, the buoyed end became detached; and, in dragging for it, the first cable was caught and broken, so that for some days the communication with Algeria was entirely interrupted. It was then found that the first cable had been shifted several miles by the action of currents; and our *confrère* apprehends that similar complications may arise in future. 27

Electrician Sept-4 1880

The Electrician Sept 4 1880

CENTRAL AMERICAN CABLES.—We hear that the Central American Telegraph Company intend to repair and put in working order their two disabled cables between Para on the Amazon and Cayenne (French Guiana), and between Cayenne and Georgetown (Demerara). These cables have long been out of use; but as they serve to connect the Western Brazilian Coast cables from Rio Janeiro to Para with the West India and Panama Company's cables from Demerara to Jamaica and Key West, they are important links in the chain of South American lines. The repairs will probably be undertaken by the ss. *Norseman* belonging to the Western Brazilian Company, and the electrician engaged for the work is, we hear, Mr. W. S. Seaton, late of the electrical staff of Sir William Thomson and Professor Fleeming Jenkin.

CABLES.—In another column we give an article which appeared in a Boston contemporary. We have reason to believe that there is little new in Mr. Chester's work. At any rate, Mackintosh many years ago patented a method of laying a relay in mid-ocean, whilst a few years ago Mr. FitzGerald patented an invention having for its object the increase of speed in cable signalling, and recently Mr. Barney has obtained a patent for a somewhat similar object. 27

ELECTRICITY.

ST. JOHN, N. B., Sept. 14.—T. S. Gisborne, Superintendent of Government Telegraphs, has arrived here, and made arrangements for laying a cable from Grand Manan to the American coast. The cable will probably be laid from Long's Eddy to Liberty Cove, on Campobello; thence from Welchpool to Eastport, the whole distance being eight and a half miles. 27

121 Mfg & Builders Sept-1880 13

THE UNDERGROUND TELEGRAPH IN VIENNA.—The cable, made by Messrs. Rattier and Co. of Paris, consists of a strand of seven copper wires 0·6 mm. in diameter, surrounded by a gutta percha covering 5 mm. external diameter, with a coating of tarred cotton-wool yarn. Seven of these cores form one cable, and protected with—1st, a tarred woollen ribbon; 2nd, a tarred hemp covering, dipped previously in a solution of sulphate of copper; 3rd, a second tarred woollen ribbon. Each core has a conductivity from 91 to 98 per cent. of that of pure copper, an insulation from 1,100 to 3,000 megohms per kilometre at 20° C., and a capacity 0·21 to 0·25 microfarads per kilometre. The weight of each core is, according to the contract, within 5 per cent. of 300 kilometres per kilometre. The tar was quite free from acid, but the hemp covering was slightly acid from being dipped in the copper sulphate solution. The cable was made in lengths of 500 metres, and laid at a depth of 1·3 metres in a box of red larch-wood, several such cables being stretched in the box, and separated from one another by a mixture of one part of Beocsinee cement and two parts of sand. Where the cable crossed the Franzenskettenbridge, the wires, to avoid damage from the vibration, were not stretched tight, but laid simply in a layer of sifted coal ashes placed in the box. A channel 0·8 m. wide and about 1·4 m. deep was dug for the wires to lie in, and the bottom made quite smooth; the depth, 1·4 m., being always followed except when gas

pipes, &c., had to be avoided. The boxes in which the wires were laid were from 3 to 5 m. long. The cable, containing seven distinct conductors, cost about £112 per kilometre, and the complete cost of making and laying £4,202 kilometres of subterranean line containing 33,431 kilometres of cable was about £5,500.—Abstract of a paper by M. Zelli, in *Electrotechnische Zeitschrift*, in *Jnl. Soc. Tel. Eng.*

Scientific Amer Sept 25 1880

~~Scientific Amer~~ Sept-25 1880 27

PERHAPS the most remarkable operation hitherto recorded in the history of submarine telegraphy is that which has just attended the work of the Eastern Telegraph Company's ss. Chiltern. In 1870 a cable was laid running off the coast of Portugal in 2,000 fathoms of water, and recently persevering efforts have been made to grapple and raise this old cable. The general idea is that a cable after so long an immersion is rotten, and cannot be raised from such immense depths, but this success will do much to dispel these ideas. The cable has been successfully grappled and raised, and was found to be as good and as strong as when laid ten years ago. To grapple a mere thread in 12,000 ft. of water may well be termed a triumph, and great credit is due to the perseverance of the company, and the ability shown by Captain Goodsall and the chief electrician, Mr. Phillips.

Nature March 17 1881 27

THE work of laying subterranean cables is proceeding favourably from Nancy to Paris. This telegraph line is composed of twelve insulated wires placed in a large tube of cast iron. For each length of 500 metres doors have been arranged so that any section can be removed and replaced without having to open the ground, which is necessary in the German system of laying the cables in a solid bed of asphalte.

Mfg & Builders Sept-1880

~~Manufacturer &~~ Builder Sept 1880

How Long a Telegraph Cable Lasts.

The life of a submarine telegraph cable is from ten to twelve years. If a cable breaks in deep water after it is ten years of age, it cannot be lifted for repairs, as it will break of its own weight, and the cable companies are compelled to put aside a large reserve fund in order that they may be prepared to replace their cables every ten years. The action of the sea-water eats the iron wire completely away, and it crumbles into dust, while the core of the cable may be perfect. The breakages of cables are very costly, and it is a very difficult matter to repair them in comparison with land lines. A ship has to be chartered at an expense of $500 a day for two or three weeks in fixing the locality and in avoiding bad weather, as cables can only be repaired in the calmest seasons. One break alone in the Direct Company's cable cost $100,000 to repair, and the last chance left to the company was to make an agreement with the Anglo-American, so that they should be protected and have the use of that company's line when their own was stopped.

Herald Aug 4. 1882.

Put the Wires Under Ground.

The successful laying under ground of the wires connecting the Central Office and Firemen's Hall is important in several respects. In the first place it affords an additional source of safety to the public—to life and property—and in the second it shows that the commercial telegraph companies can, if they choose, do away with the unsightly poles which disfigure so many of our leading streets and avenues. The only question involved is really one of expense, and as long as the companies are allowed to save money in this way so long will they continue to disfigure the streets. Even Washington is ahead of New York in this respect. Her authorities have put a stop to the erection of poles, compelling a company, which was recently given the right of way through the city, to carry their wires through the sewers. This is practicable in this city above Fourteenth street—at least so the Commissioner of Public Works says. We shall, of course, never have a reform until a stringent law is passed on the subject; but considering that the companies as a rule make the statutes to govern themselves the question is, How shall we get the law?

ATMOSPHERIC ELECTRICITY.

By David Flanery.

Prof. Kirchhoff relates two other cases of disruptive discharge, one where the lightning jumped from a rod across an air space of eighty metres to a water-pipe which it burst, by the mechanical effect of the stroke; the other in which the lightning followed the rod down into the earth and sprung to a gas-pipe a metre distant, damaging it considerably, owing, as he says, to the fact that the joints of the pipe were packed with hemp and tar instead of the usual lead. Father Secchi described similar accidents some years ago, and arrived at like conclusions, so the professor's idea is in accord with other distinguished scientists.

Consider the Stralsund church and these two cases together. If the generally accepted fact that the resistance of the earth in the telegraphic circuit is about 12 ohms be true, remembering that in overcoming resistance sparks do not follow Ohm's law, and not forgetting that they do follow the law of potential, how can one explain the passing of a spark through such spaces, the smaller of which has an infinite resistance, when that of the rod and earth circuit is so small? It seems more reasonable to think that the action was the reverse of that stated, as may appear from what follows; that the pipes conducted the electricity to the church, and more of it than the rod was able to discharge by its points, and hence the lateral strokes and damage. This view is supported by the well-known fact, stated by Prof. Kirchhoff, that the point whence electricity springs suffers most injury. The pipes were injured in both cases, nothing is said of damage to the rods.

There is another consideration: telegraphers know that there is great derangement of apparatus, more flashing and melting of lightning arresters when the storm is two or three miles off, than when it is actually overhead, and that the ground plate of the arrester often shows stronger marks of discharge than the line plate. If all strokes were from the clouds then, when the storm is overhead, we should, before the electricity has an opportunity to be diffused through the earth, receive most damage; but this is not our experience.

Furthermore, granting that all the discharges are from the clouds, what becomes of the electricity after it enters the earth? The reservoir theory is here suggested. But is the earth as a reservoir for electricity any way different from the ocean as a reservoir of water? Immense volumes of water are poured into the ocean daily, but it does not appear to increase, for evaporation on an equally great scale is going on at all times, and thus, what came from the atmosphere at one place goes back to it at another. So equilibrium is maintained, and so there is no more water or vapor in the world to-day than there was at creation. Does electricity move in a similar

FAST SPEED WORKING ON CABLES.

Telegraphic Journal

Perhaps at the present time no field of invention offers to electricians so rich a prize as that of submarine telegraphy. It is well known that the duration of a cable in good working condition is comparatively brief. It follows, therefore, as a matter of necessity that the profit on the large capital outlay, entailed in laying a cable, and the requisite reserve fund, be secured during a short period varying from ten to possibly twenty years. Now the carrying power of a submarine line being limited (although, thanks to the ingenuity of Mr. Stearns and the Messrs. Muirhead, less so than formerly), it follows that while the above conditions last, the tariffs must remain quite up to the existing rates if they are to be at all profitable.

It is, however, a matter well worth consideration whether the carrying power of cables cannot be increased by the employment of a quadruplex or multiplex system, or by the employment of automatic fast speed apparatus. The latter seems the more likely field for successful invention, and although we believe something has been attempted in this direction, no success has been attained as yet. The idea of the new American Cable Company recently organised in New York, to submerge a translator or repeater in mid ocean, is undoubtedly a correct one, but the practical feasibility of the project is more than open to question. It is hardly too much to say that no piece of mechanism has ever yet been devised which can be trusted to work with certainty to an indefinite period without human supervision. As is well known, the cause of the retardation of signals in submarine cables is the inductive effect, which causes the cable to hold a charge which has to be got rid of after each signal has been sent and before another can be transmitted. Could some arrangement be devised by which this charge can be "wiped out" at *both* ends of the cable simultaneously, a great advance would be made towards solving the problem of fast speed submarine telegraphy. It seems to us that there is considerable scope for invention in this direction.

Scientif Amer. June 25 1881.

Telegraph Cables in Sewers.

An important experiment looking to the disuse of telegraph poles in cities is being made in Washington, D. C., by the Mutual Union Telegraph Company. Having received permission to run their wires through the common sewers of the city the company began the work of placing the wires June 6. The wires which are needed for the city service and for connection with lines outside the city are twisted cable form and covered with a non-conductor and waterproof coating. Outside the city limits these wires emerge from the sewers and join those placed upon poles. The cable made of the twisted wires is attached firmly to the arched roof or top of the sewer, and thus raised above all interference from water, except in case of floods. The cables are laid by men enveloped in rubber clothing and provided with safety lanterns, provision being made for conducting fresh air to the workmen by means of India-rubber tubes attached to their rubber suits. The wires are passed down through the man holes of the sewers.

The Marvels of the Telephone.—The Telephone discovering Faults in Submarine Cables.

[From *L'Electricite*.]

We have received from a correspondent in India the description of a truly marvellous experiment, to which we cannot too earnestly direct the attention of our readers. The original idea belongs to Mr. Allen, assistant to Mr. Schwendler, the skillful director of the Anglo-Indian system; but the application of it has been made by Mr. W. P. Johnston, employed in the active service.

The officers of a telegraph ship having to repair a submarine cable, belonging to a line which possessed several cables, found themselves very much embarrassed to choose the faulty one. They had, in fact, raised one, but the question arose was it the one to be repaired, or was it one of those which were in a good state of repair.

The solution of a problem which seems completely beyond our means of scientific investigation has been made in an unexpected manner by Mr. Johnston. It is known that the submarine cables are surrounded by an iron wire rolled in spiral form, which serves to protect the conductor of copper, from which it is separated by one or more envelopes of gutta-percha. A length of about 12 yards of the cable having been hoisted on board, Mr. W. P. Johnston attached one extremity of the wires from a telephone to the armor at each one of the ends of that section, and listened attentively to the sounds produced. Every time that the conducting wire of the submarine cable was used to send a signal, the iron wire was traversed by an induced current, of which a portion, passing by the derived circuit of the telephone, caused a movement of the diaphragm. Thus the signals sent inside were repeated on the outside of the cable. It was then incontestable that the submarine cable wire, whose length was 442 miles, worked very well and needed no repairs. But what was more valuable than this fact was a discovery in physics which was made at the same time and in a manner entirely unexpected.

The force of the derived current was augmented in proportion as the points of contact between the telephone wires and the cable armor were brought nearer together. At a distance of two yards, the sounds were quite distinct.

We will add the numerical data sufficient for judging of the conditions of an experiment, which contain, perhaps, the germ of an indefinite progress.

The circuit of the telephone had a resistance of 2½ ohms.

The copper conductor of the cable had a resistance of 23 ohms.

The armor of the cable was composed of 12 wires of galvanized iron weighing 924 lbs. per mile. The resistance of each wire being 7 ohms, that of the whole number was 7½ ohms.

The resistance of the 2 yards of wire sufficient to give a current was then 0.66 milliohms, or 1-3800 of the resistance offered by the circuit.

It therefore follows that, to be heard in the telephone, only 1-3800 of the derived current produced by the primary current passing over the conductor in the cable is required.

The exterior currents, whose existence is thus revealed in an iron wire plunged in the bosom of the ocean, are they not susceptible of other applications more useful? May we not hope that some day cables may be worked without insulation? It is a question that we content ourselves with placing before practical telegraphers, and to which we shall probably not have to wait long for a response. But we doubt that in the number of marvels related of the telephone there will be found any more surprising than the above.

CORRESPONDENCE.

27

VAN CHOATE'S NEW CABLE SCHEME.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of Oct. 23 you devote a leader to the criticism of certain propositions made, as to the working of submarine cables, by Mr. S. F. Van Choate. That article is, permit me to say, not characterised by the usual good judgment attending the statement of facts from the editorial sanctum; for the reason that only half the truth is given.

In the first place, perhaps I owe an apology for bringing myself into the question, but I feel that as one of the reporters on the performances of Mr. Van Choate's instruments, and as a frequent contributor to the columns of your journal, I should not allow erroneous opinions to pass current.

Your editorial speaks of two patents as to the division in length of long submarine cables, one by Macintosh, the other by FitzGerald, as interfering with Van Choate's claims in this subject. Unfortunately for these inventors, Van Choate's patents for the division of a cable (as far as division is alone concerned) antedate theirs; in fact, he, and neither of the others, ranks as the first inventor.

Even were this not the fact, Van Choate's more recent inventions are not affected by either of the patents in court. First, Macintosh distinctly refers to a local battery of sufficient constancy, enclosed in a proper manner, as being sunk into the ocean. A suitable battery, it is scarcely needed to tell your readers, has yet to be invented. Van Choate's relay needs no local battery *in situ*; his relay is altogether of another order to that indicated by Macintosh.

FitzGerald's scheme certainly employs a common feature with that of Van Choate's instrument, namely, an electro-magnet; but unless FitzGerald wants to raise a Page-patent dispute in England such as has disgraced this country, I fear his claim would be untenable. Further, FitzGerald and Van Choate's inventions are entirely dissimilar, because the action of the primary circuit in FitzGerald's scheme does not call upon any fresh source of power in the secondary circuit, as does Van Choate's, for which reason Van Choate's invention must consistently have greater power at disposal. Again, FitzGerald must lose in power on his secondary circuit by the amount or value of the coefficient of induction between his primary and secondary circuits. Now, for the weak currents used in telegraphy, and especially in submarine telegraphy (and with the large soft iron cores necessarily attending FitzGerald's plan, which cores can never even approximate saturation), this coefficient will be only a very small fraction of unity, reducing as multiplier the efficiency of such a system of signalling to very low limits. In Van Choate's system, on the contrary, the received signals may be considerably stronger than those sent.

But Van Choate's invention does not alone depend on submerged relay. It embraces a type-printing system, based, as regards its signals, on a very careful study of the phenomena of induction as indicated by Sir W. Thomson in his well-known investigations. It is sufficient for this letter to say that this system works perfectly on an artificial cable we have here; this cable is of 772 microfarads capacity, and of 4,000 ohms' resistance, with an insulation of about 2 megohms. So, under these conditions, we have every reason to believe that there is a great step made in these matters by an American inventor.

Your criticism as to the small attention given to submarine cable working by the many professors who have seen these instruments I am obliged to notice, because I thought that the claims advanced by so-called "cable-doctors," who, when a poor cable is broken down, tell its symptoms by some unwritten laws of sympathy, were long ago exploded. The phenomena of cable induction are well enough known to those who have a practical laboratory training, or are so easily perceived that it would be farcical on this ground to say that such men as Barker, Dolbear, and especially Trowbridge were incompetent judges because they had not served apprenticeship on board a cable vessel, or in a cable factory.

I do not consider myself at liberty to give unauthorised a more detailed answer to your criticisms, but I shall be pleased at an early date to place before your readers the particulars of this invention. It may be said that Mr. S. F. Van Choate is well known on this side the Atlantic as a telegraph engineer, who has constructed and successfully financed some of the longest lines on this Continent.

My former experience with those in this mundane sphere who make the construction of electric spheres (and cylinders) their business is not so glowing as to warrant that I should blindly tack my faith to any invention or inventor, but in this instance (as you have favoured me by excepting me from the roll of ignoramuses in submarine telegraphy) I have no fear in asserting my full belief in all that the talented and scrupulous investigators have said about Mr. Van Choate's system.—Yours, &c.,

PAGET HIGGS.

Boston, Nov. 10, 1880.

The Electrician, June 11, 1881.

ABSTRACTS OF SPECIFICATIONS.

39. STREET CURBS AND GUTTERS FOR THE RECEPTION OF TELEGRAPH WIRES, H. J. Haddan.—Dated 4th January, 1881.—(A communication from J. D. Townsend.)—(Complete.) 4d.

This relates to a conduit for telegraph and other conductors, consisting of a flanged case or chamber forming a street curb, a parallel flanged chamber forming the gutter, the chamber being suitably connected together at the sides and ends, and covered with a removable cover forming a step and gutter piece for the curb and gutter.

39

CABLE-LAYING IN GUIANA.

BY J. MUNRO, C.E.

On the 27th of May, 1874, the telegraph ship "Hooper" arrived off the Para mouth of the Amazon River with a cargo of submarine cable on board. It was a time of extraordinary activity in cable-laying; and in the two preceding years the "Hooper" had laid cables all along the coast of Brazil from Para to Rio de Janeiro. Her present mission was to link Para, the capital of Brazilian Guiana, to Cayenne and Demerara by cable, and thus to connect the Brazilian cables to those of the West Indies and the United States. It was a trip, as it afterwards turned out, fuller of incident, perhaps, than any other cable expedition except the first Atlantic.

The "Hooper" is a large vessel of over 5,000 tons burthen, built expressly for the work. It had been the practice hitherto to take an ordinary steamer and fit her out with cable-tanks, testing-room, and laying machinery in the best manner possible; but the "Hooper" was the first ship specially built for cable-laying, as the "Faraday," of Messrs. Siemens Brothers was the next. She belonged to Messrs. Hooper and Co., the india rubber cable manufacturers, of Millwall, and the cables she carried were manufactured by them for the Western and Brazilian Telegraph Company, after the designs of Sir William Thomson and Professor Fleeming Jenkin, the company's engineers.

Her crew, like the crew of every telegraph ship, consisted of the captain, officers, and seamen for navigating the ship, the cable engineers and "cable hands" for attending to the mechanical operation of laying, and the electricians engaged in making the electrical tests of the cable. The captain, the cable engineers, and the electricians, inhabited the saloon, while the officers of the ship occupied the mess room, and the cable hands shared the fo'castle with the sailors, not, however, without a good deal of jealousy and grumbling on the part of Jack.

There is generally very little doing on a telegraph ship during the outward voyage. The real work of the expedition only begins with the laying. We whiled away the time in novel-reading, in writing essays for our "Literary and Scientific" Society, or in after-dinner talk on the quarter-deck at sunset. The saloon passengers of a cable ship are generally men of the much-wandering Ulysses type, men who have laid cables or put up land-lines in various quarters of the world, and who have their scraps of romance and adventure to reveal. It was pleasant as the sun went down, and fired the golden west before us, to sit and smoke on deck, and listen to snatches of real experience, instructive, exciting, humorous, pathetic, sometimes even poetical, and always interesting—tales of blockade running, of Australian exploration, of camping out in Persia or the Cape, recollections of Garibaldi's expedition or the Indian Mutiny, reminiscences of Venice, Cairo, Hong Kong, or Stamboul, interspersed with many useful "wrinkles," curious facts, and accounts of marvellous natural phenomena. There was a good deal of banter and repartee, too, and discussion of all manner of themes, as well as anecdotes upon all subjects.

We had amongst us a representative of the first Atlantic cable expedition, who bore a prestige something similar to that of a survivor of the Balaklava charge, and who loved nothing better than to find himself the centre of a circle of admiring hearers. It was his custom then to favour us with some select morsels from the unwritten history of that great undertaking. He was wont to tell us of the wonderful coolness of Sir Samuel Canning, the engineer of the expedition, who at that disastrous moment when the end of the cable parted at the stern of the ship, to vanish into the Atlantic, turned quietly to our storyteller, and simply said, "Have you got the time, Mr. B." We were never tired of hearing, too, of that critical time on board the "Niagara," when the "continuity" signals from the "Agamemnon" failed, and it was feared that the cable was broken between the two ships. There was an anxious gathering of the scientific chiefs in the little testing cabin, where the end of the cable was connected up to the galvanometer for testing. It was like a surgical consultation over some fatal accident. Professor Thomson, seemingly overpowered by the thought of failure, kept his eyes rivetted with a half-despairing look on the mirror of the testing instrument, as one watches for a last breath from the lips of a dying man; Mr. Bright stood by, biting his nails as if he were bewildered; Mr. Canning was grave, but self-possessed; the captain, from behind, dubiously watched the testing, while the sailors crowded round the door and peered over each other's shoulders with confused and wondering faces. After some minutes of painful suspense a feeble quiver of the needle was observed, and this death-bed scene was turned to one of almost frantic joy—the cable was sound!

When we left Gravesend on May-day, the nightingales were singing in the Kentish lanes, and the meadows were speckled with daises. We halted a few days at the superb island of Madeira, with its vine-clad terraces and violet atmosphere; then, after a run of a fortnight over the deep blue of the Central Atlantic, and through, perhaps, the purest atmosphere on earth, we entered the dull bottle green waters off the Amazon mouth, and could distinguish the dark fringe of the immense primeval forest which shrouds the valley of the great river up to the base of the Andes. Dull green and savage near at hand it was broken up into clumps of trees by the mirage of the tremulous heated air, and gradually dwindled away into the distance.

Off the Indian fishing village of Collares, whose red-tiled roofs nestle at the roots of the lofty forest, we took on board a pilot from the lightship, and proceeded up the Para, or southern mouth of the river, towards the city of Para, which is situated seventy-five miles from the mouth, and is the only port for the vast and inestimably rich and fertile plains of the Amazon.

It was a burning tropic day, and, as is usual in this equatorial region, there was thunder in the air. All around rolled the brimming yellow flood of the river full up to the dense wall of forest on the left, and the shaggy Eden-like islands on the right. Down its rapid tide many waifs from the interior, cedar logs, dyed reeds, and broken lilies were floated past. The sun streamed down his vertical rays, and sultry clouds hung about the horizon. Close under the main bank of the river where the water appeared cool, smooth and glassy, we could see by our glasses the canoes of native fishermen gliding under the towering forest like tiny paper skiffs, the red brown skins of the half naked Indians contrasting savagely with the dull green of the tropical foliage.

Nature here is on a wild and magnificent scale. At its mouth the Para river, as the southern branch of the Amazon is called, is thirty-six miles wide; at the City of Para it is still twenty miles wide, but the channel becomes so filled up with islands below and above Para that the river there appears only a few miles broad. These islands, which have originally sprung up out of sand banks, are virgin wildernesses treacherously beautiful, and sometimes so overgrown with vegetation as to resemble a tangled hop garden.

In the evening, while the setting sun from behind the western forest filled the broad river scene with his rich golden lustre, we came to anchor in front of Para between the city and the islands, out in mid-stream. Para stands on a small promontory of low land jutting into the river. It is a chimneyless tropic town, with flat, red-tiled roofs, and whitewashed walls, interspersed with the glittering crests of palm trees, and the luxuriant foliage of the bread-fruit, while here and there rise the ornate towers and cupolas of some grey Portuguese convent or cathedral. All behind, the primeval forest hems it in, ever ready to encroach and regain its lost ground. The anchorage in front was full of native craft, manned by Indians and negroes, American schooners with flour from Boston, European ships lading rubber and Brazil nuts, indigo, and cacao, and the white and scarlet river steamers of the Amazon Company, which ply between Para and Manaos at the mouth of the Rio Negro 800 miles up stream, and carry down the produce of the interior, cinchona, indigo, sugar, cashass (rum) in exchange for jerked beef from the island of Marajo, clothing and provisions.

On board the "Hooper" we now began to make arrangements for laying the cable. The salt water which had been allowed to soak the cable during the voyage was now pumped out of the cable tanks, leaving the cable in a damp coil at the bottom of each. Some "faults" or flaws in the insulator, which had developed themselves in the hot atmosphere of the tropics, had to be cut out, and the pieces of cable to be laid had to be made up into one length.

A submarine cable, as is well known, consists of a stranded copper wire or conductor enveloped in a thick skin of gutta percha, india rubber, or some other insulating material. The wire conducts the electric current, and the insulator confines the current to the wire, or, what comes to the same thing, prevents it from escaping to the sea water, or "earth," as it is called. The wire and insulator form the "core" or part of a cable essential to the transmission of the electric current, but in order to guard the core from mishap and to render it strong enough to bear the strain of laying and repairing operations, it has to be strengthened by an outer sheathing of tarred hemp and galvanised iron wires. The shore portion of a cable being that most liable to mishap from anchors, storm-waves, or boulders, it is usual to sheathe the "shore end" very heavily. The "main" cable, or deep sea portion, is generally deposited at great depths out of harm's way, and is, therefore, lightly sheathed; while the "intermediate" type, which comes between these, is of intermediate strength. These three types of cable are stored in the tanks in the order in which they are to be paid out. The "Hooper" had three tanks, and paid out, of course, from her stern; therefore the Para shore end occupied the stern tank, the Para-intermediate, main, Cayenne-intermediate, and Cayenne shore end following in order.

The laying of a submarine cable has been reduced to a science. The arrangements on board a telegraph ship are now in the main everywhere the same. The cable is usually laid under the entire responsibility of the contractors who make it. To them belongs the ship, and all the operations of laying are conducted by them, subject to the approval of a staff of engineers, representing the company's interests, who are temporary guests on board. The head of the expedition is the engineer-in-chief, who directs by aid of his assistants the mechanical operations of laying. Under him are the chief electrician, whose duty it is to see that the cable is laid in good electrical condition, and the captain of the ship, whose office is simply to manœuvre the ship in accordance with the requirements of laying. A fully equipped telegraph ship must be fitted with the necessary machinery for carrying and laying the cable, with proper electrical apparatus for testing it, and also with the most approved means of navigation; for it is of the utmost importance in case of future repairs to be able to lay down on a chart the exact course of the ship, since this is also the exact route and position of the cable. Besides her cable tanks she has force-pumps for filling sea water into them or drawing it off: she has a huge laying machine, consisting of a friction brake, strain dynamometer and drum; she has a powerful steam winch for coiling over cable from one tank to another; and in addition to these she has a store of grapnels for hooking the cable in the sea, and buoys for marking positions or buoying the end up at the surface when it becomes necessary to do so. Projecting from the stern there is fitted up a large deeply-grooved wheel or pulley of iron which revolves on a fixed axle, and is generally surrounded by a narrow platform with a railing round it. This is the "stern sheave" or pulley over which the cable passes on its way to the sea; and this, as well as the red-painted buoys lashed along the taffrail, is one of the distinguishing features of a cable steamer.

While the cable was got ready for laying, we electricians had plenty of leisure to land and ramble about on shore. The "City of Belem," or "Para," was founded as long ago as 1616, by the Portuguese Cadeira. At that time the Amazon, or "mighty Orellana" was a fabulous river, flowing through the magical regions of El Dorado, whose banks were peopled by a warlike tribe of Amazons, and whose sands were sprinkled with diamonds. Time has disenchanted it of its imaginary wealth and glory, but the real natural riches and wonders of its forests which have been revealed have amply atoned for the loss. Last century, when the Portuguese looked to Brazil as their future seat of empire, they built large convents, palaces, and public buildings at Para, for they anticipated that it would become the emporium of the Amazon valley. At the present day these grand edifices are falling to decay. Para has, until lately, been declining rather than advancing. The revolution of 1835 checked its development to an extent from which it has not yet fully recovered. The native Brazilians, leaguing themselves with the Indians, who had been hunted and enslaved by the Portuguese settlers, attacked the latter and overthrow the Government. It was years before the country was tranquillised, and the consequent insecurity to life and property, together with the heavy impost duties imposed by the Brazilian Government, has repelled immigration. Within the last twenty years, however, there has been a marked revival of trade and enterprise. The dilapidated city has been in great part renovated.

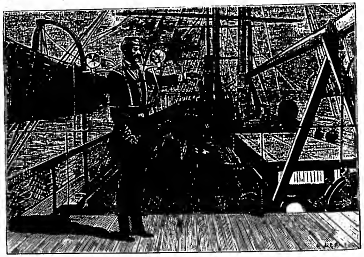
APPAREIL ACOUSTIQUE

POUR RECONNAITRE EN MER LE LIEU DE PRODUCTION D'UN SON

Depuis longtemps, la fréquence des collisions en mer par temps de brume, et les épouvantables catastrophes qui en résultent, ont attiré l'attention des marins; bien des physiciens ont cherché le moyen d'assurer la sécurité de la navigation au milieu des brouillards, qui rendent si dangereux le parcours des routes océaniques, surtout dans les régions où elles se trouvent le plus abondamment fréquentées. C'est dans le but d'éviter les rencontres, que les bâtiments sont pourvus de cloches, de trompes et de sifflets à vent ou à vapeur. Ces instruments, qui doivent servir à signaler la présence d'un navire dans un rayon plus ou moins étendu, ne remplissent qu'imparfaitement le but : le bruit qu'ils font, est parfois perçu, mais avec une netteté insuffisante pour qu'on puisse juger nettement de la direction d'où proviennent les ondes sonores. Le nouvel instrument que nous représentons, est dû à un Américain, le professeur Mayer. Il est destiné à déterminer la direction et aussi la distance approximative de la trompe ou du sifflet d'alarme.



Emploi du nouveau topophone de M. le professeur Mayer.

L'action de cet appareil est basée sur ce fait que, si deux ondes sonores de même hauteur parviennent simultanément aux oreilles, le son perçu est doublé; si, au contraire, les deux ondes sont séparées par une demi-longueur d'onde, les deux sons se neutralisent et l'oreille ne perçoit rien. L'appareil se compose de deux boîtes résonnantes, montées sur un support qui les réunit; il repose sur les épaules de l'observateur comme les bretelles d'un porteur de lait. Le fond des deux boîtes est réuni aux oreilles par un tuyau flexible de caoutchouc dont on peut réduire la longueur à volonté. L'observateur donne aux tuyaux la même longueur de chaque côté, et il tourne sur lui-même jusqu'à ce que les résonnateurs lui transmettent le son maximum. Il est alors en face de la source sonore. En raccourcissant l'un des tuyaux de manière à séparer deux ondes par une demi-longueur, il doit entendre le son minimum, et cette épreuve doit confirmer la première. En faisant diverses observations dans une même bordée, et à l'aide d'un calcul très simple de trigonométrie, il peut se rendre compte de la distance approximative de la cloche d'alarme ou de tout autre instrument faisant entendre un son.

Cet appareil, qui a reçu le nom de *topophone*, a récemment été expérimenté par la marine militaire des États-Unis; notre gravure en donne le mode d'emploi tel qu'il doit être usité à bord d'un navire[1].

[1] D'après l'*Engineering*.

127

rate of three miles an hour. His enormous battery consisted of sixty-four cells, containing twenty square feet of platinum.

This was in all respects an apparent failure, and the philosopher was thoroughly disheartened while standing unwittingly on the threshold of a brilliant success. In the first place, he attempted the impossible in trying to get a great power economically from any battery; and, in the second place, no powerful battery had yet been invented. But his engine was an excellent one, and the subsequent inventors failed to equal it until Gramme, of Paris, discovered that one of his own dynamo-electric generators would act in the reverse direction as an admirable motor.

The interval between 1839, when Jacobi's motor was abandoned, and 1870, when Gramme's machines came into notice, was occupied by a large number of inventors, who brought to their work a world of ingenuity and all the learning of all the sciences save one, but that one was the only key to success—*electro-magnetic induction*. In the meanwhile Mr. Joule, himself a former seeker after this nineteenth century philosopher's stone, dashed the hopes of his co-inventors by his demonstration of the Conservation of Energy. This magnificent work, the grandest perhaps in the history of science, was immediately made the basis of a series of experiments, which it would be out of place to detail here. Suffice that Mr. Joule proved to the satisfaction of all scientific minds that the mechanical energy of the electrical current, produced by the consumption of one pound of zinc in a Daniell cell, is equal to 1,106,160 pounds raised to the height of one foot; in a Grove cell, which has $1\frac{3}{4}$ times the electromotive force of Daniell's, to 1,893,600 pounds raised to the height of one foot, or, in the sulpho-chromic acid battery now before you, which has double the electromotive force of a Daniell's, 2,212,320 pounds raised to the height of one foot. Dr. Scoresby and Mr. Joule state their conclusions in the following sentence: "Upon the whole we feel ourselves justified in fixing the maximum available duty of an electro-magnetic engine, worked by a Daniell battery, at 80 pounds, raised one foot high for each grain of zinc consumed." This is about half the theoretical duty. In a Grove battery the same proportion would give 144 pounds, and in the sulpho-chromic battery 160 pounds, raised one foot high for each grain of zinc consumed. This result was immediately compared with the duty of the best type of steam engine per grain of coal, and it was found that one grain of coal lifted 143 pounds one foot high. But zinc, at the most favourable computation, costs ten times as much as coal, and the force it yields is therefore, as 143 is to $\frac{160}{10}$, or about nine times as costly.

The conclusion instantly drawn by the scientific world was that electricity produced by the consumption of zinc can never compete with steam, but it is the purpose of this paper to collect certain facts which will show that this conclusion is erroneous.

History is teeming with instances where noted scientific men declared that there was nothing attainable beyond their immediate vision, and proved with sarcastic argument and brilliant syllogism that further advance in certain directions was impossible. So it was with the steamship. An eminent scholar and mathematician, some fifty years ago, proved beyond the peradventure of a doubt that an ocean steamship was an absurd dream. His calculations showed that one could not be built large enough to carry her own coal across the Atlantic. And so these gentlemen, having proved that electricity produced by zinc is nine times as costly a source of power as steam produced by coal, predict that electric motors can never usefully compete with steam engines. Now, man-power, according to the tables of a well-known English engineer, is one hundred times as costly as steam; nevertheless there are several circumstances in which we prefer men. It is certain that we would never employ men if we could get a steam engine to do the work more cheaply, and it is equally certain that we would not use electricity where steam was applicable. But steam is not applicable, for reasons which will be given later in detail, to work in which we require a small amount of power in constant readiness for action. In these cases—such as jewellers' lathes, dental engines, and the various tools of small machine shops, which employ but a small force of men—we have never been able to find a source of power adapted to the work which, if not as cheap in proportion as large steam engines, should yet be more economical than human energy. The fact is that whereas, according to Joule, the best electric motors are nine times as costly as steam power, human energy is eleven times as costly as electricity. And, inasmuch as human energy, which is one hundred times as costly as steam, is frequently preferred to steam engines, *a fortiori* electricity will often be preferred to steam; and it will require no argument to show that the human energy thus saved from exhaustion in the exercise of brute force can be devoted to a higher use.

CABLE-LAYING IN GUIANA.

BY J. MUNRO, C.E.

(CONTINUED FROM PAGE 82.)

The usual rate of paying out is about five miles an hour. Night and day the cable is running out of the ship at this rate, and extending behind in a slant through the water until it reaches the bottom, at a point varying with the depth, but often ten miles in the rear. A constant watch is kept on the cable in the tank to ensure its leaving the latter freely, for were several flakes to stick together and catch in the crinoline, such is the momentum of the moving ship that the crinoline would be torn up and the cable most likely snapped asunder and lost in the sea. To prevent any accidents on deck through this or some other cause, a man stands near the stern sheaves with an axe in his hands ready to cut the cable asunder at once and relieve the strain. The velocity of the cable and the strain upon it are also constantly noted.

In the electrical testing room a perpetual test is applied to the whole cable to detect any flaw that may break out in the insulator the moment it appears, and signals are exchanged every few minutes with the electricians left on shore to make sure that the copper conductor is intact, and that communication is kept up. The soundness of the insulator is certified by a spot of light from a mirror galvanometer on a darkened scale, and an electrician is told off night and day to watch this spot. So long as it remains steady on the scale all is right, and when relieved from his four hours' duty the watcher may write "O K" (telegraphic parlance for "all correct") in his log book; but should the spot suddenly fly off the scale something is wrong, a fault has broken out, and heat once rings the alarm bell. Then the officer on the bridge signals the engineer, the engines are stopped, the cable is restrained, and the ship brought to rest. There is much excitement on board, from the engineer-in-chief down to the sailors; for the fault may be overboard in deep water, two or three hundred miles behind the ship. In this case it will be necessary to cut the cable and buoy its end, then go back to where the fault is supposed to be, grapnel for the cable on the bottom, haul it up, and cut out the faulty piece. If it be within twenty miles of the ship, she will most likely proceed backwards, hauling in the cable again as she goes, until she arrives at the fault. On the other hand, the fault may be in the length of cable on board the ship not yet paid out, and little time or money need be sacrificed in getting it eliminated. The first thing to be done in any case is to cut the cable near the stern of the ship, and test the length in the sea and the length still on board separately, and in this way localise the fault. Several stories are told of faults having broken out while the weary electrician on watch had dropped off to sleep; and it is said of one green youth who was on duty when a fault occurred that he coolly reported in his log book at 1:15 a.m. "spot vanished"—and went to sleep until he was awakened at four bells by the man who came to relieve him.

While the electricians and engineers are on constant duty, observing all the symptoms of the cable, electrical and mechanical, the navigating officers are no less busy, fixing the position of the ship, by the sun during day, and the moon and stars during night. Soundings, too, are regularly taken every few hours to determine the depth and character of the bottom. The temperature of the water, and the velocity of currents, are also occasionally measured, in order to learn as much as possible of the place in which the cable is deposited.

The morning after leaving Pará we had paid out all the shore end, and were again off the mouth of the Amazon. It was a charming morning. The bottle-green sea was shot with sunbeams which illuminated its depths and showed the glistening silt-like motes. Here and there the olive surface was crested with the foam of breakers, or dappled with the purple shadows of the clouds. White gulls wheeled and gleamed under the cloudy sky like flecks of snow. The violet nautilus scudded along like a bubble before the light sea breeze, and thousands of medusæ, resembling Chinese lanterns, tumbled about at all depths. In the afternoon, shortly after dropping the pilot, we ran into one of the treacherous sand-bars which infest the mouth, and stuck fast, the screw churning up the sand and froth among the delicate pulsating medusæ, which seemed to have crowded round to look at us. The ship, which a moment before had been gliding like a sea-bird over the painted ocean, now lay as helpless as an iron box. All the efforts of the screw were unavailing to get us off the bank, so a kedge anchor was put out, and we waited for the evening flood tide. During the daylight which remained, a boat was lowered to buoy the cable, but the tide rose so rapidly that the boat was caught under the cable, and to prevent her being swamped the men on board were obliged to cut the cable, and in their alarm they cut on the wrong side of the buoy, so that the Para end was lost in the sea. That night a terrible squall of wind and rain came on; the "Hooper" creaked and strained and bumped every now and then against the bank. A very high tide was running up, and this, with the counter flood of the river running down, made the sea very rough. The shouts of the seamen and operations in the darkness, the raging waves, the lightning which flashed out of the gloomy sky in which a new moon was struggling, made a wild enough scene, and the shuddering and groaning of the huge ship as she was knocked against the ground added a spice of danger. About 11 p.m., however, just when the tide was at its full, the engines backed her off, and we were clear. Next day the ss. "Great Northern," the repairing ship of the Western Brazilian Company, sent to us from Pará, recovered the lost end of the cable and the buoy for us, not without some difficulty, owing to the high sea which tossed the cutter like a cockleshell, and the sudden squalls which came down every now and again.

After this little episode all went well for a few days, if we except a false alarm of a "fault," which turned out to have been occasioned by some neglect on the part of the electricians stationed at Pará, "the men at the other end," who generally come in for as much blame as possible on a cable expedition. If the men at the other end heard all that is sometimes attributed to them on board the ship, they might feel inclined to retort in language not quite Parliamentary; but it is useless to attempt to storm through a submarine cable, all the emphasis is lost.

Mile after mile was run out day and night, until the stern tank was emptied, and it became necessary to shift to the tank amidships. The cable being all in one piece, this was effected by slowing the ship until the bight came up out of the empty tank, and straightened itself on the pulleys. It is generally a moment of some anxiety while the bight straightens, for

HISTORICAL MEMORANDA ON SUBMARINE TELEGRAPHY.

BY F. C. WEBB, M.I.C.E., M.S.T.E. 27

(CONTINUED FROM PAGE 21.)

1854 (continued).—In this year Messrs. Glass and Elliot, of East Greenwich, made twelve miles of cable, which was laid between Sweden and Denmark. It had three No. 16 conductors, each covered to No. 2 with G.P., and ten No. 2 galvanised iron wires for sheathing. This was, it is believed, the first cable made by Messrs. Glass and Elliot, which firm, combined with the Gutta Percha Company, forms the present Telegraph Construction and Maintenance Company. In this same year this firm manufactured a cable to be laid between Spezzia, in Sardinia, and the island of Corsica, 110 miles long, and one to be laid between Corsica and the island of Sardinia, across the Straits of Bonifacio. The pattern of these cables was six conductors of No. 16, covered to No. 1, with G.P., and sheathed with twelve No. 1 ungalvanised iron wires. These cables were laid in June of this same year from the s.s. "Persian." Mr. R. Brett was responsible for the laying of these cables, and engaged Mr. Thomson, formerly Mr. R. S. Newall's principal engineering assistant on such expeditions, to assist in the work. The depth of water (350 fathoms) was much greater than had previously been dealt with, and the cable being a heavy one strong break power was required. Two drum breaks were used. Each drum had two break straps, one on each side of the part round which the cable passed. These drums were placed one behind the other. The cable was to make five turns round the foremost drum, and then pass on to the after drum, round which it was to take four turns. The four break handles had tackles on them fast to the deck, so that the handles could be boused down, and thus the break power was considerable. There were wood blocks on the break straps, and the author believes the drums were 8ft. diameter. There was no stern wheel, but only a saddle over the taffrail. Some kind of movable knife was used, which was held by two men, but this was strongly objected to by Mr. Thomson. The following account is from some notes given to the author by Andrew Nelson, a steady-going Swede, who was present on board during the laying, and who for many years was foreman under the author on board the "Monarch," where the poor fellow was eventually killed (after the author left the ship) by being dragged into the picking-up machine on a fine summer's day, when cable was being picked up in the North Sea.

The "Persian" arrived at Spezzia July 21, and landed end at 9 a.m., and payed out till 10 p.m., when they brought the ship up by the cable for the night. July 22, at 4 a.m., something wrong with cable ashore (electrically), and after consultation a steamer was sent back to Spezzia to see what was the matter, and found the clerk asleep and the cable disconnected; commenced paying out again, and went on until 2 p.m., when they had a broken wire, which carried the knife under the drum and flattened the cable. They then cut the cable, and removed the damaged part, spliced up, and proceeded at 4 p.m., until 10 p.m., when they again brought up by the cable for the night. July 23, 4 a.m., commenced paying out, and soon stopped to "ship the other drum" (that is, it may be supposed that up to this only one of the drums was used, and that now the second was placed in circuit by having turns taken round it). In stopping, they damaged the cable, and in repairing it damaged also the taffrail. Laid to for the night. July 24: Commenced paying out, and got to Cape Corsica at 10 p.m., and brought the ship up for the night. July 25: Landed the end at 11 a.m., 91 miles having been paid out in distance of 71 miles.

It appears that the cable often surged alarmingly on the drums. There was no holding back gear, except a nipping arrangement, made by something like a pair of nut-crackers. The fleeting knife, not being fixed to the frame, as had always been the case on all former expeditions, but only held by two men, appears to have been the principal cause of the accidents. The cable, however, was eventually laid in good electrical order. The deepest water previously encountered had been 180 fathoms, viz., on the Portpatrick and Donaghadee line, and here the depth crossed was about 350 fathoms, so that the final success was certainly creditable, and indeed no cable of so heavy a type has, we believe, been ever laid since in such deep water. The electrical tests of this cable were under Mr. H. V. Physick, formerly assistant engineer to the Electric Telegraph Company. The cable lasted good for many years, but when it failed it was never repaired. These cables, made by Glass and Elliot, had a left hand lay, Newall's cables having been right hand.

In the latter part of this year one of the Hague cables failed about thirteen miles from the Dutch coast. The ports on the Dutch coast would soon be frozen, and it was considered unsafe to have a steamer working on that coast under the circum-

Iron, Jan 14. 1881

SOCIETY OF TELEGRAPH ENGINEERS.—The Council of this Society have made such arrangements with regard to the Library, at 4, Broad Sanctuary, Westminster, that it has been practically thrown open to the public, and for the convenience of those who are not able to use the Library in business hours it will remain open till 8 p.m. on four evenings a week.

THE ATLANTIC CABLES.—A new double line of cable is about to be constructed and laid down between America and Europe. The capital has been subscribed in New York. The construction of the cables has been entrusted to Messrs. Siemens Bros, Charlton-near-Woolwich, and will afford employment for 2000 hands for the next twelve or eighteen months. The length of the cable to be manufactured is 9000 miles.

THE DUPLEXING OF SUBMARINE CABLES.—In duplexing long submarine cables it was found that one great point to be aimed at is to carefully reproduce in the artificial cable which balances the working cable an exact imitation of the first 300 miles or so at each end of the working cable, both as regards the resistance and electrostatic capacity of each consecutive mile of cable in its proper relative position. For this purpose, says the *Electrician*, the "section books" containing the tests of each mile of cable before it is added to the cable, are consulted, and the artificial resistances and inductive resistances forming the artificial one made to correspond—the remaining portion of the working cable being represented in the artificial cable more in the gross than in exact detail. This shows that the labour expended on the careful compilation of exact tests during manufacture is not thrown away, but is becoming of increased importance. So sensitive is the balance to this exact representation of the first few hundred miles of cable, that even a slight decrease in insulation at one spot within that distance can only be rebalanced by a similar decrease of insulation at exactly a corresponding spot along the artificial cable; and this seems to open out a new and accurate method of determining the distance and magnitude of a small fault of insulation. In fact, for finding the distance of a fault in a cable, we should have for one side of the bridge an artificial cable having electrostatic capacity and resistances exactly similar to the cable under test when perfect.

the repair until next spring.

The Mexican Telegraph Cable.

IT is expected that the lines of the Mexican Telegraph Company, connecting with the Western Union Company at Brownsville, Texas, thence to Tampico and Vera Cruz, by cable connecting with government lines in Mexico, will be in operation about February 1st. Due notice will be given of tariff rates, etc., when the cable is laid. Jan 12 '81

the arrangement with the new French Cable Co.

Journ Tel ... 1881

Atlantic Cables. Jan 14 1881

THE lengths of the several cables between the United States and Europe and their locations are given as follows: The three Anglo-American cables now in use run from Ireland to Newfoundland, 1,850 miles, and from Newfoundland to Sydney, over 300 miles—a total distance of 2,150 miles each; the Anglo-French cable from Brest to Duxbury, by way of St. Pierre, is about 3,320 miles long; the Direct United States cable from Ireland to Torbay, and from Torbay to Rye Beach, 2,360 miles; and the new French cable from Brest to Louisburg, 2,430 miles, from St. Pierre to Cape Cod, 880 miles, and from Brest to Penzance, 151 miles—a total length of about 3,401 miles.

Of the cables laid by the Anglo-American Company, the one put down in 1865 was broken March 11, 1873; and finally abandoned February 1, 1878; that laid in 1866 was broken January 13, 1877, and abandoned July 27, 1878. The latter cable, except the shore ends, was renewed last summer at a cost of £222,300; it is now called the cable of 1880. The cable laid in 1873 was broken April 2d, 1879, and was repaired in the same month; it is now in operation. No break has yet occurred in the cable laid in 1874. Of the three cables now working, which were laid by the company, one has been down over six years and another over seven years. The Erlanger cable, under the management of the Anglo-American Company, was laid in 1869; it was broken in the following May, and several times since the same accident has occurred. It was last repaired in August, 1879, having been broken February 22 in that year, but it was again broken last month.

The cable of the Direct United States Company was laid in 1874, and has been broken twice: the first time, January 4, 1879, on the ocean side near Torbay, and in February, 1879, in the Rye Beach and Torbay section. Both breaks were repaired, and the cable is said to be now in good condition. The cable of the new French company has been down about a year. It was broken May 2, 1880, near the Island of St. Pierre, and repaired the same month; the section between Cape Cod and St. Pierre was broken November 21, 1880, and is now repairing.

THE NEW ATLANTIC CABLES.—The following paragraph in some shape or other has been going the round of the papers during the past fortnight. A Woolwich paper gives it thus:—"The chief topic of conversation in Woolwich this week has been the news that Messrs. Siemens Brothers have secured an order for the construction of a double line of cable between America and Europe. The length of cable to be manufactured is 9,000 miles, the largest order probably ever given in the history of ocean telegraphy. It is stated that the firm will find employment for 2,000 hands for 18 months." We have reason to believe that Mr. Jay Gould is now in London, and that the order for the two new cables has actually been given.

Iron March 18 1881

27

SUBTERRANEAN CABLES IN FRANCE.—The work of laying subterranean cables is proceeding favourably from Nancy to Paris. This telegraph line is composed of twelve insulated wires placed in a large tube of cast iron. For each length of 500 metres doors have been arranged so that any section can be removed and replaced without having to open the ground, which is necessary in the German system of laying the cables in a solid bed of asphalte.

Herald. Aug. 3. 1881.

UNDERGROUND WIRES.

The underground telegraph communication between the Central Office and Fireman's Hall was yesterday established. In the past, when the wires were at the mercy of the weather, it frequently happened that messages could not be conveyed, and the co-operation of the police with the firemen in cases of conflagration was impeded. Now it is intended that, in spite of all obstacles, news will be transmitted readily from one headquarters to another. In the new system the wires are enclosed in a layer of chemical compounds which are not subject to changes of temperature. There is no possibility of their crossing, as was the case with those upon the poles, and there is no possibility of either the wire or the material around it rotting. For some time the concern who have the patent for the new system have been at work laying their wires underground from Firemen's Hall to the Central Office, and yesterday they completed the work and brought the wire to the stoop of Police Headquarters. To-day it will be connected with the telegraph system under Superintendent Crowley's charge, and it is possible that it will transcend the old telegraphic method and be used entirely by the police force. The system has already been used by private parties in Brooklyn, and is said to have accorded general satisfaction.

THE NEW AMERICAN CABLE.

LONDON, August 11.—I have the pleasure to-day of sending you over the new American cable some particulars of interest as to the arrangements for throwing the cable open for business to the public. The American Cable office in London, which will be ready for occupation very shortly, is in the most admirable position at No. 21 in the Royal Exchange, on the corner of Threadneedle street and opposite the little square in which Mr. Story's statue of George Peabody, the American banker and philanthropist, smiles benignantly on the passing crowds in front of the windows of the Scottish-American Insurance Company. As I came out of the office this morning I stood for a moment looking at the statue and could not help recalling the resolute, unobtrusive way in which George Peabody some twenty years ago, with his partner, now Sir Curtis Lampson, took up and carried through the first great ocean cable enterprise when all others had abandoned it. They generously left the credit and a good deal of the profit of the undertaking to your ubiquitous fellow-citizen, Mr. Cyrus W. Field. But though most of the capital with which the work was done was English capital, that capital was raised and new life was put into the enterprise by these two transplanted Yankees, George Peabody and Curtis Lampson. The first, after resting from his labors in Westminster Abbey, was sent to his long home in his native Massachusetts, under the English flag, in an English man-of-war. The second, having established himself with all his property and interests in this country, has accepted a British baronetcy, offered in recognition of the success of the ocean cable. But both were true Americans at heart, and there is something, therefore, both pleasant and appropriate in the establishment of the office of the first really American cable under the very eyes, as it were, of George Peabody's statue. Of course, business and not sentimental considerations determined the choice of the site, but a company with such prospects before it can afford itself the luxury of a little sentiment. The first of the two transatlantic cables of the company was formally handed over by the contractors, Messrs. Siemens Brothers & Co., on Friday last, on which day the guarantee term of thirty days of perfect testing subsequently to the laying of the cable expired. Since the connection between Whitesand Bay and Canso was completed hourly

electrical tests have been made by the electricians in charge. They report the cable to be the very best ever laid under the Atlantic Ocean. A speed of transmission has been attained on it 30 per cent. in excess of the guarantee and 20 per cent. in excess of the speed ever attained on any other ocean cable. All that now remains to be done before opening the offices of the company for business is to complete the quarters for the company's staff at both ends and the land line connections in England. The company's staff will be made up of men picked from the whole cable service of the world. The quarters for the American staff will be at Canso, in Nova Scotia, and as the season fortunately favors them, and the work, thanks to the energy with which it has been pushed, is now substantially six weeks ahead of the time contemplated in the contracts for making the cable, it is expected, I learn at the London office, that the American staff will be comfortably under cover and ready for business before the 1st of September. The English staff are established already at Whitesand Bay, a remote but very beautiful spot near the Land's End, on the wild and picturesque west coast of Cornwall. There the English shore end of the second cable of the American Company has already been laid. The cable steamship Faraday is now taking on board the deep-sea portion of this second cable at the works of the Messrs. Siemens Brothers & Co. at Woolwich, and will soon proceed to sea to lay it. It is possible indeed, that both the cables of the new company will be laid and in operation before the time at which, judging from the experience of the European companies, we should have been justified in expecting to see the first one actually in use. To complete the English connections by land of the American cable, the Postal Telegraph Department is now constructing a system of special land wires which will furnish direct working circuits from Whitesand Bay in Cornwall (there is another Whitesand Bay, let me remind your readers, on the south coast of Devonshire not to be confounded with this) to London, 281 miles; to Liverpool (where the Company has its offices at No. 5 Exchange Buildings), 320 miles, and between London and Liverpool, 206 miles. This will secure duplicate circuits for the business of the company between the cable landing in Cornwall and London, one being available in case of an interruption of the other. From what I have seen and learned myself to-day it appears to me quite clear that Pender & Co. and the British Globe cable monopoly may as well make up their minds to see the new American company under way and in successful operation by the 1st of September at the latest. All the people in charge of the new enterprise have a quick, alert, quiet and expeditious way with them which seems to me of evil augury for the old concerns. Americans here take a great deal of patriotic interest in the work, for which I do not blame them. They have a right to be gratified, I think, at the prospect of seeing a large part of the profits of the ocean cable business at last diverted into the pockets of the American public, which has done so much to build the cable business up and to make it profitable. How profitable it has been made you may infer from the recent half-yearly reports of the Anglo-American and the Direct companies. Those reports show for the six months ending June 30, 1881, a gross revenue of $2,000,000. The total working expenses at a liberal estimate have not exceeded 20 per cent. of this amount, and the two companies have been enabled besides paying their dividends to add the snug little sum in round numbers of $550,000 to their reserve funds. Furthermore, while the English companies have been doing this business, the French company formerly managed by Count Dillon, which forms the third member now of the great European Pender cable pool, has taken in during the same period not far from $500,000 of gross revenue. With a much smaller capital invested, greatly improved cables and a thorough-going active American administration in charge, the new American Cable Company may be expected to swing even more than its natural proportion of the profits of this rapidly increasing business back to your side of the water, from which they are so largely drawn.

LORD SALISBURY AND THE GOVERNMENT.

Panama Star & Herald Apr. 14. 1881.

THE CABLE.

The recent operations of the *Grappler* in repairing the cable near Colon, are reported as having been entirely successful. The cable was picked up at the precise spot where tests, previously made, showed it to be injured. It was not broken, but was frayed and untwisted, and generally used up. The injured portion was cut out and new cable added, to supply its place. Subsequent tests showed another difficulty 340 miles from Colon, although it is not known whether the line is broken or not, as the Holland Bay station is probably not advised of operations in progress here the *Grappler* having come from Barbadoes direct. Certain indications would seem to show that tests are in progress at the other end of the line, as faint signals are observable in Aspinwall, but not sufficiently clear to amount to a demonstration. One of the electricians of the party went to Kingston by the *Don*, yesterday morning. When he arrives he will get hold of the machine there and endeavor to work through. Should he fail in doing so the *Grappler* will underrun the whole line to Jamaica, and complete its effectual repair.

THE AMERICAN CABLE.

Where It Lands in England and How the Steamer Faraday Does Her Work.

[SPECIAL CABLE DESPATCH TO THE WORLD.]

WHITESAND BAY, CORNWALL, August 20.—We are expecting to welcome to-night or to-morrow morning the cable steamship Faraday which sailed from Woolwich yesterday at 8 A. M. with 1,500 miles, being considerably more than half, of the second Atlantic cable on board. The shore end was buoyed off this cove some time ago and awaits her arrival. She will take it up at once and start westward to lay it. With ordinary weather she ought to get the whole length she now carries laid and buoyed in about eight days. As you know, the Faraday, after the Great Eastern, is the largest vessel afloat, being 360 feet long, 52 feet beam and 30 feet deep. She is so deep, in fact, that whenever she lies in the Thames they have to dig a cradle for her at Woolwich in the river-bottom to float her. The wonderful speed with which she does her work is due to the perfection of her equipments. She is fitted up with electric lights of two patterns. Her deck is lighted with the new Siemens light, of the effects of which on the ocean, even before it had attained its present perfection, Mr. Laurence Oliphant gave you such a striking description after his voyage home in the Faraday three years ago. Her main saloon is lighted with the Swann electric light. Thanks to this perfect illumination, the men on board can work night and day with equal ease, and such is the excellent adjustment of her machinery that it makes little difference to her what the weather may be or the rolling of the sea. She has three cable tanks—fore, aft and amidships—filling the whole width of the ship. These are of iron and are water-tight, and they are so arranged that as fast as the cable is paid out water can be taken in as ballast to steady the ship. The cable is coiled into the bottom of the tanks from the inside to the outside. It is paid out in reverse order from the outside to the inside. The bight of the cable is brought up through a kind of cage called a crinoline passed over a revolving wheel, carried along down a shoot astern about thirty feet in length, and then passed between three sets of super-posed wheels, which act either as drags to retard or spurs to accelerate the paying out of the cable according to circumstances. Emerging from these, the cable is passed three times around an eight-foot drum, from whence it goes to a dynamometer fixed about thirty feet further astern. From this it is carried over the stern of the vessel by a wheel so rigged as to pay the cable out at any angle. When the weather is very rough they take on extra bight in the cable from the drum and carry it forward about one hundred feet through another triple set of wheels and another dynamometer. This prevents any sudden strain from snapping the cable. The drum acts as a brake and an automatic recorder which gives the amount of strain on the cable as it passes over, and the strain can be so regulated as to secure an uniform strain, not varying far from 5 per cent. The Faraday carries a crew of 200 picked men and about twenty-five officers and electricians. She is commanded by Captain Maypee. Mr. John R. Brittle is chief engineer of the expedition. Mr. Humstone, who came out in the Faraday from America with the first cable to represent the company, was so well satisfied with the arrangements of the ship and the organization of the enterprise that he has returned to the United States. An officer who came out in the Faraday tells me that she always makes her own soundings on every voyage. She has Sir William Thompson's patent sounding machinery on board, and she has crossed the Atlantic so often that she now sails chiefly by her own chart, which is more exact than any Government chart in existence. She is a kind of floating farm, too, carrying her own live stock, bullocks, sheep, geese and fowls of all kinds, so that her people live like fighting-cocks. The weather-wise here to-day tell me to expect her to-night. She landed the first cable by moonlight at 10 P. M. on the 9th of June last. She arrived off Whitesand Bay on Sunday June 5. But this is a wild coast when the sea runs high, and she had to lie in Mouse Bay until the 9th before the weather would allow her to land the cable. I should be glad to see her come, but a man might easily be in a worse place to wait for her. No words can describe the sublime grandeur of this granite coast, from the Land's End to Cape Cornwall, and Whitesand Bay is perhaps the most picturesque indentation. It is a historical bay, too, for King John landed here when he came back from Ireland, six or seven hundred years ago, and the unhappy Perkin Warbeck came here on his last expedition to maintain his claim to the English crown. The quarters of the Cable Company here are established in the bight of the bay, about three and a half miles from the Land's End, upon land leased from a parson who is a local "swell" of importance. They stand a little up the direct road from Penzance to the Land's End, and are reached by a cross-road which diverges from the main road opposite a remarkable-looking educational institute and just above the two queer little local hotels. Of these hotels one is occupied all the year through, the other, which is almost on the verge of the shore, serves as a kind of summer resort. The local wits speak of them as the "First Inn and last Out." The road to the cable quarters passes some straggling huts and a few little cottages and runs very steeply down-hill to what is called Sennen Cove, where a patch of slate comes into the granite. This is a charming place which Stanfield would have been delighted to paint, picturesque with fishermen's black boats, old nets, and at certain times of the day with fishermen and fisherwomen as picturesque as the boats and the nets. They are a strange stalwart, primeval sort of race, these Cornish folk, and the women rule them by sheer strength as much as by the usual graces of their sex. When the Faraday came here in June she sent a boat ashore to pick up a pilot on a Sunday morning. The boat's crew came on an old Cornishman, who offered to find a pilot for them. He led them to one of the huts I have spoken of, but could not get in. After much knocking at the door they got speech through a window with an old fellow within, who explained that his wife had locked him up and gone off to church, and that the visitors must see her if they wanted to get him out. They posted off to the church and with some difficulty induced the old lady to come out and consent to release her husband.

She seemed to be an amiable giantess, so the officer ventured to ask her whether she had incarcerated her husband in order to keep him sober. "Oh, no," she said—with much simplicity, "it's only to keep the women away from him."

From this point to Penzance, about nine miles, the telegraph part of the cable is carried on iron posts. From Penzance two lines pass through Plymouth up to Exeter. At Exeter one line diverges eastward through Honiton and Axminster to reach London by the Great Western line. Another runs northward by Taunton and Bridgewater to Bristol, whence it proceeds to Liverpool and from Liverpool again goes eastward by the Midland Railway to London, making thus, you will see, a double circuit for the cable connections in England. I was in Liverpool last week and saw the cable offices there. They are at A 5 in the Exchange Buildings, directly under the great news-room and next door to the Anglo-American office. The rapid progress of the new American Company has waked up cable people in England and in Europe generally to the growing importance of the American business. The Dacia, Sir Charles Bright's old West India ship, has just sailed with a cable some four or five hundred miles long, constructed at the Silvertown Works for a Spanish company, which is to be laid from Cape San Antonio in Cuba to the Belize in British Honduras.

End of "News from Europe."

new American Cable Company may be expected to swing even more than its natural proportion of the profits of this rapidly increasing business back to your side of the water, from which they are so largely drawn.

All that now remains to be done before opening the offices of the company for business is to complete the quarters for the company's staff at both ends and the land line connections in England. The company's staff will be made up of men picked from the whole cable service of the world. The quarters for the American staff will be at Canso, in Nova Scotia, and as the season fortunately favors them, and the work, thanks to the energy with which it has been pushed, is now substantially six weeks ahead of the time contemplated in the contracts for making the cable, it is expected, I learn at the London office, that the American staff will be comfortably under cover and ready for business before the 1st of September. The English staff are established already at Whitesand Bay, a remote but very beautiful spot near the Land's End, on the wild and picturesque west coast of Cornwall. There the English shore end of the second cable of the American Company has already been laid. The cable steamship Faraday is now taking on board the deep-sea portion of this second cable at the works of the Messrs. Siemens Brothers & Co. at Woolwich, and will soon proceed to sea to lay it. It is possible indeed, that both the cables of the new company will be laid and in operation before the time at which, judging from the experience of the European companies, we should have been justified in expecting to see the first one actually in use. To complete the English connections by land of the American cable, the Postal Telegraph Department is now constructing a system of special land wires which will furnish direct working circuits from Whitesand Bay in Cornwall (there is another Whitesand Bay, let me remind your readers, on the south coast of Devonshire not to be confounded with this) to London, 291 miles; to Liverpool (where the Company has its offices at No. 5 Exchange Buildings), 320 miles, and between London and Liverpool, 206 miles. This will secure duplicate circuits for the business of the company between the cable landing in Cornwall and London, one being available in case of an interruption of the other. From what I have seen and learned myself to-day it appears to me quite clear that Pender & Co. and the British Globe cable monopoly may as well make up their minds to see the new American company under way and in successful operation by the 1st of September at the latest. All the people in charge of the new enterprise have a quick, alert, quiet and expeditious way with them which seems to me of evil augury for the old concerns. Americans here take a great deal of patriotic interest in the work, for which I do not blame them. They have a right to be gratified, I think, at the prospect of seeing a large part of the profits of the ocean cable business at last diverted into the pockets of the American public, which has done so much to build the cable business up and to make it profitable. How profitable it has been made you may infer from the recent half-yearly reports of the Anglo-American and the Direct companies. These reports show for the six months ending June 30, 1881, a gross revenue of $2,000,000. The total working expenses at a liberal estimate have not exceeded 20 per cent. of this amount, and the two companies have been enabled besides paying their dividends to add the snug little sum in round numbers of $550,000 to their reserve funds. Furthermore, while the English companies have been doing this business, the French company formerly managed by Count Dillon, which forms the third member now of the great European Pender cable pool, has taken in during the same period not far from $500,000 of gross revenue. With a much smaller capital invested, greatly improved cables and a thorough-going active American administration in charge, the

UNDERGROUND TELEGRAPH WIRES.

THERE appears to be an increasing tendency to lay wires for telegraphic and telephonic purposes underground, in place of suspending them overhead. So far as the general public is concerned this tendency is viewed with decided approval, there being a widespread and well-founded idea that the existing network of suspended wires not only disfigures the thoroughfares of our towns and cities, but is a serious danger. In London this is especially the case, some of the streets of the City being covered with perfect cobwebs, so to speak, of these wires, some of which have on more than one occasion broken with fatal results to pedestrians and passengers on the outside of omnibuses. On every public ground, then, the alteration is to be warmly welcomed, and there are few, if any, sound practical reasons why every aerial wire should not be brought down and buried. The only drawback is the allegation that some loss of electrical conductivity arises in subterranean lines; but this is surely a relatively slight matter on short circuits, such as are chiefly affected in this manner. In Germany thousands of miles of military and other telegraph wires are now underground, without any complaints as to the effects of "earth," and in the United States the lines are being boxed up in a non-conducting mixture, composed of pitch, pulverised glass, and other materials, with the greatest success. What can be done elsewhere can be effected here. Once the authorities feel the pressure of public opinion the change will speedily follow. When that happens there ought to be a good demand for cast or wrought iron pipes in which to convey the guttapercha-covered wires.

RECENT INVENTIONS.

ABSTRACTS OF SPECIFICATIONS.

4482. CABLES FOR TELEPHONIC PURPOSES, *E. George and J. B. Morgan.—3rd November,* 1880. 6d.

This invention has for its object the obviation of the effects of induction, to effect which the inventors cover the telephone wires with an ordinary insulating substance, and imbed or combine with this insulator wires or metals. These wires or metals, or the outside surface of the insulating substance, are connected to earth by conductors

4482

at intervals. The non-induction insulated or open wires or metal may be laid around, parallel to or otherwise in connection with each insulated conductor, so that when placed together such conductors form a cable; this is strengthened by a metallic core in the centre, and is surrounded by a network or riband of metal. It is carried on supports or standards. The drawing shows the system of suspending the cable.

N. Y. Herald, Oct. 1st 1881.

Put the Wires Under Ground.

The practicability of putting the telegraph wires under ground is being amply demonstrated by the German government. More than two hundred cities and towns of the Empire are now connected in this way, and the operation of the wires is, we are told, a complete success. The experiment is of very great practical interest and value to our own country, where the question, particularly in the large cities, has been agitated for many years. Thus far the wires are under ground in, we believe, only one of our cities—Washington—and there they are carried along in the sewers by a company which could not obtain the privilege of disfiguring the streets. No difficulty that we have heard of is experienced in the working of those lines. The only obstacle in the way of securing the same results all over the Union is the disinclination of the companies to incur the extra expense. According to the statement of the present head of the Department of Public Works the sewers of this city are large enough above Fourteenth street to admit of the wires being carried through them, but in the absence of compulsory legislation on the subject the old plan is continued, and some of the most beautiful portions of the city are made hideous by the erection of clumsy contrivances which are a disgrace to our civilization. The planting of another telegraph pole in any portion of the metropolitan district should be absolutely prohibited.

THE SECRECY OF "GOVERNMENT TELEGRAMS" SECURED BY THE USE OF THE AUTOMATIC TELEGRAPH.

To the Editor of the Telegraphic Journal.

SIR,—In reference to the intercepting or taking off messages from telegraph wires, as referred to in the resolution introduced on the 23rd of March last in the House of Representatives at Washington, involving the want of secrecy in the handling of Government telegrams, Mr. Edward Clarke, in his reply to the Hon. James E. Blaine, Speaker of the House of Representatives, very truly says that in some cases the wires connect with instruments in hotels, and that all the wires connect with various cities and stations between Washington and the northern cities.

Permit me to say that the trouble does not end here, and that Mr. J. G. Smith's suggestions, as regards the use of silent Morse instruments in any form, offers no security whatever against the abstraction by unauthorised persons of telegrams from the through wires at way stations, or at any point on a line of telegraph by any ordinary Morse operator as well as by experts, and, therefore, does not, in my opinion, meet the requirements, so far as it relates to the abstraction of Government *or other* despatches.

The only security lies in the use of the "automatic telegraph," for the following reasons:—First, by causing the pulsations of electricity to travel at any rate of speed above that at which a Morse expert is only able to interpret the same either by feel, taste, or by sound. I here refer to the American automatic telegraph, which has been in practical public operation for over two years between Washington and New York. It is an impossibility for the greatest Morse expert to abstract by feel, taste, or by sound, at any point on this line, during automatic transmission of a telegram, as in such attempts it becomes to the party "*ignotum per ignotius.*" And in regard to the office, the *modus operandi* is that of silence; and it matters not how many persons may be in each office during the transmission or reception of a message, by *my* automatic system no one but the copyist need know its purport; and, to meet the copyist's case, Mr. Edward Clark suggested the propriety of passing a law fixing a penalty or punishment on any person who may divulge any message sent by telegraph.—I am, &c.,

GEO. LITTLE.

735. T. A. Edison, of Newark, New Jersey, U. S. A. *Improvements in Circuits and Instruments for Chemical Telegraphs.* Dated February 27, 1873.—This invention is to increase speed on long chemical telegraph lines and render the marks clear and distinct. The counter current set up in an electro-magnet as it discharges itself upon breaking the circuit is employed in a shunt or branch to neutralise tailings. Two or more stylus or pens in main line with shunt circuit and magnet in each are also used. Drop copies are taken by a division or branch and the magnet and receiving instrument or a vessel of water into which the circuit wires are introduced. With a very rapid circuit breaker and resistance in the main line, the transmitting instrument is placed in a circuit connecting at both sides of the resistance. An induction coil is employed as a relay for the automatic transmitting system, the same sending a secondary current to the receiving instrument or to another induction relay. Reaction batteries are introduced upon the line or in branch or shunt circuits, to clear the line of surplus electricity, the power of the same being much less than that of the main battery, and the poles opposed.

Condenser for the Little Automatic Telegraph.—In order to use a chemical telegraph in connection with electro-magnets in the circuit, it is requisite that a condenser should be used in connection therewith. After much experiment to obtain the best form of condenser, Mr. George Little, consulting electrician to the Automatic Telegraph Company, informs us that the condenser he prefers to use with the electro-magnets, in order to avoid or lessen the disturbing influences of extra currents, &c., is a modification of M. Planté's liquid condenser, and consists of two thin leaden plates, of about ten inches square surface, between which is a thick piece of flannel, saturated with glycerine, so adjusted as to offer about seven times more resistance than that represented by the helices of each electro-magnet, the whole being enclosed in a strong flat mahogany box, and hermetically sealed with paraffin.

Correspondence.

Aug 76

To the Editor of the TELEGRAPHIC JOURNAL.

SIR,—I notice in your issue of the 15th inst. a review on some portion of the contents of No. 11, Vol. IV., of *The Journal of the Society of Telegraph Engineers*, and noticing some remarks on a communication by a Mr. Edison, on the imperfect contacts which occur in signalling with *rigid points* by a Bain's printer—please do me the justice by permitting me, through the columns of your journal, to say that a *non-rigid* stylus, made from No. 30 wire, and about one inch in length, was used by me, assisted by Professor Farmer, on the 19th August, 1870, on a line built for my system between the cities of Washington and New York, since which time *non-rigid* styluses have always been used in connection with my apparatus for cheap telegraphy, and clearly shown in my English patent, of date April 22nd, 1872, at letter *i*, fig. 19, sheet 8; as also in my American patent of September 2nd, 1873, at fig. 23, sheet 3.

Yours truly,

GEO. LITTLE,

June 30, 1876. Richmond, Va., U.S.

Tel Jour Aug 1. 76

2,803. R. MORLEY, London.—"Improvements in electric telegraphs." Dated August 9th, 1875. (A communication).—This invention has for its object to avoid the unevenness and spreading of colour in the signs made on chemically-prepared paper in some automatic telegraphs. It does so by discharging a battery upon the receiving apparatus at the same time that the line is traversed by currents from two batteries alternately positive and negative. An arrangement is also described for transmitting signals at a high rate of speed at the same time in opposite directions over one wire.

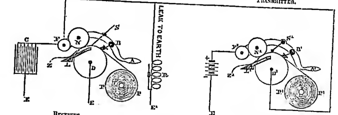
10

11

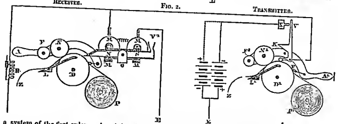
LITTLE'S RAPID AUTOMATIC TELEGRAPH SYSTEM.

THE devices employed in this system are, as will be seen by reference to the diagrams, classed under two heads—a chemical writer, which is involved in

RECEIVER. FIG. 1. TRANSMITTER.



RECEIVER. FIG. 2. TRANSMITTER.



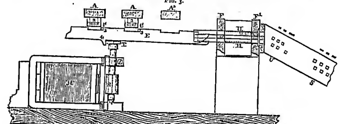
a system of the first order, and an ink writer, in a system of the second order.

It should be stated that any number of the Little automatic apparatus may be run, all at varying speeds, on the same circuit, without in the least interfering with the legibility of the writing, as the characters on each receiving instrument assume their own relative proportions with mathematical accuracy.

The Automatic Telegraph Company, of which the Hon. George Harrington is President, have now this system in operation, by virtue of an agreement with Mr. Little, between the United States Capitol at Washington, D.C., and some of the most important commercial cities in the country.

In the chemical writer (Fig. 1) D D' are flanged drums, which may be set in motion by any of the well-known devices, but preferably by a small belt leading to a crank-handle, to be worked by hand power, the labour required being very slight. P P is a roll of chemically-prepared paper; P' P' a roll of

FIG. 3.



paper having telegraphic symbols, perforated or embossed on the same. The end of each roll of paper, Z Z', is passed over the drums, and held in firm contact with their surfaces by the nipping

Proceedings of Societies.

OCIETY OF TELEGRAPH ENGINEERS.

rdinary meeting of this Society (the last meeting ously to the summer recess) took place on nesday evening, the 13th of May. Mr. Latimer occupied the chair.

o discussion on Mr. Langdon's paper "*On the y and Preservation of Telegraph Poles,*" which been adjourned from the 25th of March, was ued.

. Langdon said that by the kindness of Mr. Culley as able to furnish specimens of that partial m of creosoting timber which was referred to in paper. Mr. Golsten had also sent one of the poles h was planted on the Portsmouth branch in 9. This was removed during the last month urpose to be brought to this meeting as an example r durability of creosoted timber. Lieut. Ramsay supplied a specimen of a Boucherised pole planted t three years ago. It was broken off short by the nd line. This supported a statement made in the r to the effect that all the preparations which n ed to arrest decay tended to destroy the flexibility e timber. During the last discussion Mr. Clark d whether any one had ever heard of a case of yed creosoted timber. That induced him (Mr. gdon) to write to several gentlemen and ask ther such a case had ever come to their knowledge. had received answers from Mr. Newman, of the don and North Western Railway; from Mr. wick, of the Midland Railway, who had had teen years' experience of creosoted timber; from Cripps, of the London, Brighton, and South Coast way, who had had six or seven years' experience; Mr. Haynes, of the Bristol and Exeter Railway, who had eleven years' experience; and from Mr. Sach, he Great Eastern, who had had twelve years' ex- ence; and they all agreed that creosote was the preservative which they had had under their ervation, and the only one which had given perfect faction. Not one of them had any knowledge lever of a decayed creosoted pole. Mr. Webber had, ever, forwarded to him a specimen of what he ed creosoted timber. It was in a state of great ay. This piece of wood was accompanied by a er, in which Mr. Webber stated that the specimen selected from numerous other pieces which were ayed to an equal extent. They had been in use n or eight years in a bridge near Totnes on the th Devon Railway. The timber was in gravelly , and in such a position that water could drain ough it under the railway. The writer added, "On other hand, last summer I saw some creosoted es cut which had been in the bed of a tidal river twenty-eight years. They were as sound as when t put in."

Mr. W. H. Barlow had called his (Mr. Langdon's) ention to an error which had crept into the paper. as stated that sulphate of zinc was used in one the processes. It should have been chloride of c. He had received a letter from Mr. Saunders ting doubt upon the statement made by Mr. Haynes o the present existence of iron socketed poles upon Bristol and Exeter Railway. He (Mr. Langdon) l entered into correspondence with Mr. Haynes on subject, and not only did Mr. Haynes adhere to statement that there were standing, at the present ment, several of the poles originally planted, but he l sent him one as a specimen. The pole which had n sent had the slots of the old arms which had n originally fixed for the No. 3 insulators, and this t identified it as one of the original poles. Mr. ods, who was connected with the same section the line on which the poles were planted, confirmed the statement made by Mr. Haynes. Hence it was only fair to conclude that Mr. Saunders must have made a mistake.

Mr. Spagnoletti said that the subject of the paper was one of considerable interest to those who had charge of pole telegraphs, because timber formed the greatest item of their expenditure. Therefore anything which would prolong the life of a pole was of great importance. His experience of several years showed him that as much depended upon the selection of the timber as upon the mode of preparing it. Good hard mountain grown larch, which had been felled in the proper season, and well seasoned before being fixed, would last from seven to ten years without any preparation. If it was very good, or extra quality, it would last rather longer. Tarring and charring, he believed, was good, as the process prevented the chance of vegetation attaching itself to the pole. There were very many persons who were opposed to that method. The system of Boucherising did not seem to add much to the life of the pole. He had placed on the table a piece of a pole which was Boucherised and planted in 1866, and was entirely decayed when it was removed in 1872. This was one of a large quantity of poles bought of Sir Robert Harvey. The trees from which they were made were thickly planted and quickly grown, and did not contain more than forty or fifty rings. He believed that one cause of their decay was that the tissues and pores of the pole were so coarse that the moisture which was attracted into the wood would cause the copper preservative compound to dissolve so that it could leak out. In some of the poles there was not the slightest trace of the preservative material, except just in the very heart of the wood. The sulphate of copper had been found very destructive to the iron-work about the poles, especially as the iron-work was of a very light character. The earth wires on the poles were generally only No. 16 gauge, and they were soon destroyed by the sulphate of copper. The same effect was produced on the stay wires and the arm bolts. Some poles might have decayed from the fact of the timber being bad or dead before the process was applied. The next process was Kyanising, which he applied to about fifty-six miles of poles, which were planted in 1855. These poles, with the exception of a few planted in the chalk, were all good to this day. An interesting specimen of Kyanising was a piece of wood which was put down as a longitudinal sleeper on the Great Western Railway in 1840, of which the sap wood was still perfectly good. He was afraid, however, that the effect of Kyanising on the light iron-work would be the same as that of Boucherising. 2 lbs. of corrosive sublimate at 3s. a lb. was sufficient to preserve 50 feet of timber, and the time required for preparing the wood was one day for the inch and one day over. According to Faraday, the corrosive sublimate combined with the sap of freshly cut wood and formed an insoluble compound; but creosoting appeared to be the best system if it was properly performed and if the timber was well seasoned. It had, however, the disadvantage of making the timber exceedingly brittle. Creosote was, however, a very awkward preservative for poles which were placed on public roads or on railway platforms, because the heat of the sun drew the creosote out. He put up some creosoted poles three years ago and found that the banks of the railway were all saturated with creosote for about a yard round the pole. The heat of the sun allowed the creosote to gravitate downwards, and it went to the point which it was wished to preserve. In the case of which he had spoken the vegetation round the pole died. Then creosote was not at all destructive to the iron-work, but he found that in some cases the creosote insulated the earth wire of the arm. With regard to iron sockets there were a good many of them in use. They were tried on the Wootten Bassel lin-

The Invention and Inventors of Automatic Telegraphy.

NEW YORK, *Aug.* 18.

TO THE EDITOR OF THE TELEGRAPHER.

I NOTICE in your issue of the 15th instant this question by "Peter Simple," "Can you tell me who the inventor of practical automatic telegraphy in this country really is?" I am led to ask if you or "Peter" think that *any one* person can honestly claim to be the inventor of automatic telegraphy, even as it exists to-day? I am also led further to ask if there *has* yet *been* invented and developed a *practical* automatic chemical telegraph system?

I am well aware that G. L., who does not know "how some things are done," etc., as well as he ought to, at least, claims to have forty-three patents, and that it is "notoriously patent" to the whole scientific world (unfortunately that does not include your humble servant) that everything belongs to him; and also claims that, "under the guidance of a mysteriously beneficent Providence, he has been made a chosen instrument" in the discovery and development of telegraphy, "thereby rendering the same *practically universal*"—a statement that no one but G. L. believes, and which he has failed to demonstrate.

I am also aware that the great inventive humbug from Jersey—familiarly known at the Patent Office as a "model maker"—claims to have *wasted* a great many "consecutive nights" in perfecting automatic telegraphy, which resulted in accomplishing just what Mr. G. Grace had been doing for a year or two.

I am also aware that he has been reissuing other people's patents, but always to himself, and, as "Peter" says, "they are numerous, but their value is not so apparent."

I am also aware of the fact that the Automatic Telegraph Company, under the Lefferts, Little, Grace, Edison patents, manage to do very good and fast telegraphing on a circuit of about 300 miles, specially constructed for the purpose, and claimed to be the most perfect line in the country; but I am not aware of any system of *practical* automatic telegraphy by which could be done, for instance, the every day business of the W. U. Tel. Co., over its long lines and cables, branching to all parts of this country, at the same rate of speed that they do it, or even do it at all—and until this, at least, can be accomplished, automatic telegraphy is not *practical* to my mind.

If this *has been* or *can be* accomplished under any present automatic system, I should like very much to know it; and if you, Mr. Editor, or "Peter," or any of your many readers will enlighten me through your columns in regard to this, "I shall not feel hurt;" in fact, "there is nobody hurt," I hope, by such a proceeding.

INQUIRER.

One of my Electro-Chemical Problems.

To the Editor of The Telegrapher.

In reference to my duplex review of the 10th inst., permit me to call attention to the following dates relating to a portion of my many specifications (some seventy) bearing fully upon the above subject, being one of several electro-chemical problems solved by myself—namely, the problem of how to neutralize a decomposing current in the chemically prepared paper of a chemical telegraph by the aid of the single row of perforations composing the telegram itself at the transmitting end of the line, or by one or more rows of perforations, and recorded in the archives of the various governments of Europe, Asia and America, and signed by me in the following order: August, 1870; August, 1871; November, 1871; May, 1872; June, 1872; September, 1872, and February, 1873.

The above specifications, involving the use, among many other salient features fully described and shown by models, as also by elaborate drawings, of a paper fillet having one or more rows of perforations and operating one or more insulated styluses, for the purpose of completing, breaking or neutralizing circuits in a chemical telegraph using a chemically prepared strip or fillet, or a sheet of chemically prepared paper.

This one of the somewhat "paradoxical problems" presented to my mind in the early part of 1859 consisted in how to open or close an extra circuit, or, to transfer, throw upon a chemical telegraph line a neutralizing or opposing current by the use only of the same single row of perforations which go to make up the telegram itself. The (in this case) single transmitting stylus itself being made to perform that extra function controlled by the perforated row of symbols in the paper fillet by opening or closing an extra circuit, or by bringing into action an extra battery, so as to act in opposition to the battery used to make the mark in the chemically prepared fillet or sheet at the receiving end of the line wire.

The above problem was practically solved by me in the early part of 1870 between the cities of New York and Washington.

In my specifications of 1872 I also describe and show that if separate reverse currents are employed the paper is made with two rows of perforations. A portion of the instrument is shown adapted to receive a message. The pen may be used upon paper in place of the ordinary stylus to mark the pulsations by decomposition in the chemical paper. Two batteries are connected, so as to make the respective currents of equal force, or the force may be varied. Positive pulsations will be sent by one line of perforations and negative pulsations by the other line of perforations, and these will be alternated according to the position of the perforations in the paper, and these pulsations are to be of a character adapted to operate the receiving instrument at the distant station. The receiving pen or stylus may also be vibrated when chemical paper is used.

Geo. Little, C. E.

The Automatic Telegraph Company.

The Automatic Telegraph Company have recently established a number of additional auxiliary offices in this city, so that persons who desire to avail themselves of the cheap rates for telegraphing established by this Company, and their facilities for prompt and rapid transmission of business, can find accommodations for so doing without the necessity of visiting the main office. The advertisement of the Company, which will be found in this paper, will show the comparative cheapness of their charges for telegraphic service, and the location of the offices.

We understand that the Automatic Company is being very liberally patronized, and gives much satisfaction to its customers by the promptness and reliability of the service rendered.

Automatic Telegraphy.—An automatic telegraph has been tried between Adelaide and Melbourne, and it is stated with considerable success.

Dec '73

The Latest Application of Electricity.—The Automatic (Fire) Signal Telegraph.

Since the time when Sir Walter Scott pronounced his eloquent eulogium upon James Watt, that "potent abridger of time and space," so marvellous has been the progress of invention in the improvement of the locomotive and the steamship, and particularly in the application of electricity through various stages of increasing serviceability, that its subject himself, hardly less than the "bard" who pronounced it, would be startled almost into incredulity by the audacious ingenuity which, in the most advanced nations, has completely transformed the aspect of their civilization. It is not our present purpose to yield to that fascinating temptation which would set us about stating in a detailed and sequential form what these developments and inventions are, but to call the attention of our readers to the latest, and, so far as we know, the most interesting and surprising adaptation of human control over the electric fluid.

17

We are indebted to Mr. W. B. Watkins for this wonderful invention. This gentleman, originally a dry goods merchant in New York city, having for several years employed himself in the endeavor to discover some means of obviating the great damage done by water at fires, on account, chiefly, of the headway made before the possible arrival of appliances for extinguishing them, in the year 1870 procured his first patent for an invention by which a fire was itself made to give an alarm in its incipient stage, thus inducing the earliest possible use of the facilities already in employment for the purpose of putting out conflagrations. Between that date and April, 1873, he took out other patents for the protection of the several improvements successively introduced, and during the following summer the Automatic (Fire) Signal Telegraph Company was formed, with the following officers and directors, who, by the way, all of them still hold their respective positions: President, John C. Beale; General Superintendent, J. E. Foun; Directors—E. W. Crowell, David Solomon, J. Boorman Johnston, John C. Beale and Wm. B. Watkins.

These gentlemen immediately entered into negotiations with the Committee on Fire Patrol of the New York Board of Fire Underwriters to secure a connection with that body, and arrangements were made whereby the Fire Insurance Patrol stations were constituted the terminal offices for the company's fire circuits, and since that time Mr. Watkins' invention has been employed as the most effective of recent accessions to the utility of this organization. The next few months were occupied in perfecting the system and apparatus of the company, and late in the fall of 1873 it commenced active operations.

Shortly after, the attention of the Board of Fire Underwriters being directed to this system, they, after careful investigation, became fully satisfied in regard to the benefits to be derived by the insurance interests from its general introduction, and accordingly adopted resolutions granting a reduction of insurance rates to all property protected by this company's apparatus.

Our readers are already aware that the Patrol is a body of firemen employed since 1839 by the Board of Fire Underwriters, and is an organization entirely independent of the city Fire Department. In case of fire they do their utmost to extinguish it, since the invention of Mr. Babcock's Extinguisher, by means of this contrivance; or, failing in this possibility, they protect, so far as they can, the endangered property by covering it with waterproof tarpaulings inside the building, or removing it into the street and protecting it there by the same means. It is plain that such an invention as Mr. Watkins' must be of incalculable value to this organization, and since its association with the Automatic (Fire) Signal Telegraph Company its usefulness has been greatly promoted.

An inspector in the service of the telegraph company is now to be found both night and day at every Fire Insurance Patrol, and his duties are to see to the instruments, and when a signal is given to communicate with the Patrol. He is anticipated in this latter duty, however, so far as indicating the necessity of the services of the Patrol goes, for the moment his bell commences to strike, the intelligent horses, who have stood ready harnessed, rush from their stalls, and the firemen have made ready to go out almost with the completion of the signal, which, as we shall presently see more particularly, gives not alone the street where the fire is located, but the number and which floor of the building is attacked. This is a great advance upon the capability of the Fire Department, which is yet dependent for signals altogether upon the old fashioned pole boxes, which merely indicate the district in which a fire has broken out.

But to explain more minutely by what means the wonderful results we have already indicated are brought about by the new Automatic Alarm: Let us suppose the case of a building in Broadway in connection with the Patrol in Murray street. It consists of five stories. Placed along the ceiling, at intervals of twenty-five feet in each of these stories, is a number of what are called thermostats. These are small instruments consisting of a brass tube, in which is placed a compound metallic coil, composed of two metals of unequal expansive and contractive power. By the action of heat upon this coil it expands until it touches an adjustable screw, which projects through the side of the tube. By this means a connection is formed with a galvanic battery through the wires by which the thermostat is connected with a larger instrument, called the transmitter, one of which is to be seen on every floor of the building. The electric current operating through a magnet in connection with the kind of clock work of which the transmitter partly consists, conveys a signal to the Patrol station. These slow beats of the bell indicate the street and number of the house from which the signal has come, and rapid strokes, immediately succeeding them, the floor. In short, all necessary particulars for the use of the Patrol are available in almost a flash from the time when the atmosphere of

SATURDAY, OCTOBER 3, 1874.

VOL. X. WHOLE No. 420.

My Last '73.

WELL, boys, I'm done with the business—
  My fingers are stiff at last,
And I'll never jerk the lightnin'
  Like I did in the days that's past.

My "battery" is busted,
  The "vitriol" all played out;
There's no more "local current"
  Than you'll find in an old cave's spout.

My "magnets" have lost their power,
  My "key" all covered with rust;
I hate to "cut out" forever,
  But I must, for I can't adjust.

I've "pounded brass" for a livin'
  Nigh onto forty years,
But the click of the "giant sounder"
  Don't come to my weary ears.

I can't go back on "paper,"
  For my sight begins to fail;
And I couldn't tell, to save me,
  A "pole" from an old fence rail.

I feel the "relay" workin',
  But cannot hear the sound.
I can't tell by these "patent fixins,"
  The "cut out" from the "ground."

To-day the "circuit" busted,
  And I done my level best
At testin'; but, to save me,
  Couldn't tell "east" from "west."

I tried to "screw up" for "X" to-day—
  For I thought he was callin' me—
But with the magnets ridin' the armature,
  I couldn't a worked with "B."

So, I says, old man it's comin',
  You've surely had your day.
When you try to "adjust" by turnin'
  The "screw" the other way.

So I wrote the train despatcher
  That my day had come and gone;
If he had another man, I wished
  He'd send him right along.

"On No. 3," he told me,
  I can see the head lights shine.
So now I say good-bye to all
  The "old boys" on the line.

Farewell! may Heaven bless you.
  I can hardly hold the key;
Tears come when I try to say it,
  My last long "73."

I. C. EDWARDS.

The Boston Industrial Exhibition.

THE fair of the Massachusetts Charitable Mechanics' Association has been open at Boston for two or three weeks past, and is very complete and successful, as the exhibitions of this association always are. They are held but once in five years, and are a notable event in New England.

A correspondent sends THE TELEGRAPHER a brief account of the electrical and telegraphic instruments and apparatus on exhibition, which will be of interest. He writes that there is nothing especially new or interesting in the applications of electricity, unless we except the remarkable magneto-machine of Mr. Moses G. Farmer.

Mr. Charles T. Williams, the well known and long [illegible] manufacturer and dealer in electrical and [illegible] Street, Boston, has a [illegible] exhibition, which [illegible] and highly [illegible] de-graph apparatus, electric bells etc., which are well made.

Messrs. Welch & Anders exhibit Anders' magneto-printer and magneto-dial instruments. The magneto-printer operates very efficiently and with considerable rapidity—as high as thirty words per minute being obtained on it.

The Gold and Stock Telegraph Company exhibit the celebrated Gray & Barton printer, and also a pair of the repeating instruments used in the business of the Company.

Mr. Edwin Holmes exhibits his well known and highly successful burglar alarm, which has been so generally introduced.

Another firm show many forms of the French annunciators and house telegraphs.

Press Telegraphing in Great Britain.—Inefficiency of the Postal Telegraph.

IN the *New York Tribune*, G. W. S., its London correspondent, writes, under date of September 5th, in regard to telegraph matters in connection with the press as follows:

Of the curious views which some people who might know better entertain about journalism, a specimen has just turned up. I find in an important periodical two references to the report of Prof. Tyndall's address. It is described as occupying eight and a half columns of *The Times*, and every word of it, we are told, "was transmitted by telegraph at an immense cost to the leading journal." The telegraphic despatch is again mentioned in the same periodical as "one of the latest wonders of journalism, the cost of which, it is manifest, must have been enormous." I quote from *The Publishers' Circular*, which, concerning itself with practical matters touching literature of all sorts, ought to be better informed about the literature of journalism, and the expense of putting it in shape to be read. There is something ludicrous in the notion of enterprise and expenditure in getting Professor Tyndall's address. Whether the address was telegraphed at all may be doubted. It was in type in London some days before the meeting of the Association in Belfast. That copies were deposited with the principal journals of London may be inferred from the fact that one evening paper published extracts from the address some hours before it was delivered. It would be odd if no copy were sent to *The Times* office, or if their Belfast correspondent did not know that one had been sent, and so treated them to a telegraphic copy. Even in the latter case the expense would not cripple the paper. The actual cost which *The Publishers' Circular* speaks of as "immense" and "enormous" would be about nine pounds sterling, or $50 in currency. I believe I have explained before that the English press gets its telegraphing done at very cheap rates. The ordinary rate for a telegram between any two places in the Kingdom is one shilling for twenty words, addresses free. When the Government took over the telegraphs, a clause was put into the act securing to the newspapers the privilege of receiving one hundred words for one shilling. That is the price they now pay. In a *Times* column of solid minion there are about 2,100 words. If telegraphed, the column comes as near as possible to $5. This is rather less than the $2,100 gold we should have the pleasure of paying the Anglo-American Company for the same quantity of matter.

It is remarkable that the London papers, notwithstanding the cheapness of the inland telegraph, do not use it freely. One reason may be the inaccuracy of it, though special efforts are made to do good work for the papers. The meeting of the British Association is more fully reported by telegraph than most others, and a statement about it, either official or from official sources, has been published. The whole number of words transmitted during its six days' session to the English, Irish and Scotch press was 405,000. The cost is not mentioned—that would reduce the importance of the event too much—but the sum which the newspapers of the whole United Kingdom paid was a little over £200. I should say that *The Northern Whig* of Belfast spent just about the same amount for its extra reporting. The Post-office desires to have it understood that some of the wires between England and Ireland are out of order. There are 22 in all, contained in four cables, and seven out of the twenty-two were under repair. The remaining fifteen were asked to transmit on the busiest night of the meeting 80,000 words—and failed. The official account remarks that some portion—it does not say how much—of the matter telegraphed was "necessarily" too late for publication next morning. The sections adjourned at three in the afternoon, the papers go to press at four or later next morning, and, if the matter was reasonably handed in, one does not quite see the force of the "necessarily." Deducting two wires for the Anglo-American Company—of which they have the exclusive use between London and Valentia—there remain thirteen wires, which were asked on this one occasion to transmit less than 600 words each per hour, plus the ordinary business, and "necessarily" failed. But the official apologist for the Department thinks that, having regard to its "vastly diminished resources," the work was "singularly well done."

Cuba Submarine Telegraph.

THE directors in their report state that the gross receipts for the half year ending 30th June amount to £7,825, ordinary expenses to £1,930, leaving a balance of £5,895. The extraordinary expenditure for the repair of the cable has, however, amounted to £21,743, absorbing the whole of the balance of the reserve fund £12,281, the above balance of the half year's revenue £5,895, and leaving the sum of £3,567 to be carried forward to the debit of the current half year's account. They regret that the result is not more satisfactory. This is to be explained by the fact that the steamship Investigator, despatched by the Telegraph Construction and Maintenance Company in the beginning of December last year, took double the time to effect the repair to the cable that was anticipated, in this way doubling the cost of repair, and at the same time shortening the period during which the cable has been at work to about three months of the current half year. The receipts since the restoration of the cable have been satisfactory, and show a material increase on those of the corresponding period last year. The whole of the new capital authorised by special resolutions passed at the extraordinary general meeting of 12th of June last, was subscribed by the shareholders, and the contract for the new cable has been duly entered into with Messrs. Hooper's Company. The manufacture of that cable is now nearly completed, and the steamship Hooper is expected to sail in the beginning of next month to lay it. Instead, however, of landing the cable at Santiago de Cuba, it has been agreed, on the suggestion of the West India and Panama Company to carry it to Holland Bay, Jamaica, that company paying for the additional length required, but without thereby acquiring any property in the cable, which will remain the sole property of this company. By this arrangement, not only will a duplicate means of communication be provided over the whole of this company's system, but the extremely important section of the West India and Panama Company, between Cuba and Jamaica, will also be duplicated—an object of only greater importance to that company than it is to this. Arrangements are also in progress whereby it is believed the differences between this company and the West India Company will be brought to an amicable settlement, and a suitable vessel provided and stationed in the West Indies for the repair of both companies' cables. The cable of the Central American Company, referred to in the fifth paragraph of the special report submitted to the general meeting of 12th June last, has only been laid thus far from Para to Cayenne. The remaining section to Demerara is expected to be laid in November, and will then complete telegraphic communication between North and South America via the West Indies—a connection which, as previously stated, is expected to result in a very large increase of traffic to this company. Notwithstanding the diminished income for the working of the past year, owing to the length of time occupied in repairing the company's cable, the prospects of the company are better than at any former period. With duplicate lines of cable from England to the United States, thence as far as Trinidad (as will shortly be the case when the cable now in course of manufacture for the West India and Panama Company has been laid), and with the communication between South America and the West Indies established, there is every reason to believe that the company will be in a position to pay regular dividends to its shareholders, and, at the same time, lay aside a substantial sum to provide for any extraordinary repair or other contingency, which can never, under these circumstances, affect the prosperity of the company so seriously as it has done in the past.

A Telegraphic Blunder and What Came of It.

MR. GIBSON, solicitor, writes to the *Times* that at the recent Assizes for Kent it became his duty to telegraph to a plaintiff and witnesses to attend the court on a particular day, and instructing them to travel by the "seven-thirty" train. The action was for breach of promise of marriage, and when the case was called on the plaintiff and her principal witness were absent. The case was so fortified by other evidence that counsel advised it should proceed, and the plaintiff obtained some damages, but not without strong and damaging observations by defendant's counsel upon the absence of the plaintiff and her family witnesses. A few minutes before the jury gave their verdict (about one o'clock) the plaintiff and her father came into court, and then produced a telegram directing them to travel by the "eleven-thirty" train—just four hours after the time appointed by my telegram. On inquiry it turns out that some one in the Post-office employ (elsewhere than at that town, though the

10

Edison's Motograph.

W. T. Sprague, replying to an inquiry regarding this instrument, a description of which is given in his book, "Electricity: Its Theory, Sources, and Applications," lately published, says:

"I wished to include in my work the latest discoveries in electricity; hence I gave a description of the motograph. But when I wrote there was no other account extant, except that which I used; nor was an instrument in existence in England. One was subsequently brought over and exhibited at the Soirée of the Telegraph Engineers, where I saw it, and therefore added a few lines in the revision of my book before publication. I clearly understood the principle of the instrument; but it appeared to me best to use Mr. Edison's own description, notwithstanding the somewhat peculiar and confused style in which it was written.

I will now endeavor to make the matter more intelligible—as to its principles, that is to say.

All recording instruments (not counting those which print in letters, though they really come under the same generic principles) consist of a roller, which supports a band of paper drawn through the instrument, and of a style or pen pressing on the paper. In the mechanical recorders, such as the Morse, this style is attached to the armature of an electro-magnet, and when a current passes it is pressed on the paper, so producing marks; when no current passes, it leaves the paper, which moves along unmarked. In some cases the reverse principle has been used, and the signals are shown by the absence of marks—that is, by spaces, instead of lines and dots. In chemical recorders—of which Bain's is the original and type—there is no magnet; the style presses continuously on the paper, which is moistened with some liquid capable of electrolysis and of union with the metal of the style when the current passes. A common form consists of an iron style and paper moistened with ferrocyanide of potassium. When no current is passing, no action occurs; but so long as a current passes, the solution is electrolysed, acts on the style, and forming Prussian blue, makes a blue dot or line on the paper.

Now Edison's discovery is based on a very simple observation, but one which he alone has noticed. It reveals a new action of the electric current, which appears to open as new a line of scientific research and of practical application as did Jacobi and Spencer's observation of the effects of the deposit of copper in the Daniell cell, which is the basis of our modern art of electro-metallurgy. He simply noticed that while the current passed *the paper became slippery*, and ran more quickly through the machine. He now tried the effect of attaching a spring to the style, and behold! mechanical motion is produced capable of varied modification. The style will ring a bell while the current is passing, or will act as a relay and send a current mechanically, repeating the signal in one or a thousand new circuits. I caught sight of the instrument standing on a table unnoticed at the conversazione,

20

THE OPERATOR.

1875

and before seeing its label, at once recognized it, and took the opportunity of a careful examination before others had discovered it. My friends laugh at me because I button holed them one after another and led them off to see something worth looking at; but after a time it was a hard matter to get a good look at it, as, once discovered, it became the attraction of the evening. The fact is that the instrument itself is nothing: it is a scarcely noticeable alteration of the common Bain's recorder. It is the *principle* which is important. Instead of a simple style or pointed rod, there is a rod fixed upon a rocking-cradle held by a spring. A thousand people might see it and think it was nothing; but it is a cradle with an infant lying in it, whose future only the few prophetic minds can catch a glimpse of; and it must be remembered that only the prepared mind can ever understand the prophetic utterances. In the vision of the Apocalypse, how often is it said, "He that hath an ear, let *him* hear." It is so in science. Edison's description of his discovery is confused in language (in fact, I suspect it has passed through the hands of two or three compositors before it reached me), and it is only he "that hath an ear" who can grasp its meaning. I think "H.R." can catch it, if he listens to the echoes of it which I have repeated; but if not I will enter into further explanation.

21

The "Ticker" in Wall Street.

Joaquin Miller relates the following scene familiar to most New Yorkers, but not to those who are less acquainted in the ways of this metropolis or the mysteries of Wall street:

"I went to a broker whom I had met at the Union Club," says Mr. Miller, "and told him what I wanted to learn. He kindly took hold of the tape which continually streams out from the 'ticker,' as the little wheel of fortune is called, which constantly records the rise and decline of stocks, and tried to explain all about it.

"I found it impossible to get interested. There were about 200 different names of stocks on the list. These were represented by one, two, or three letters, or figures, or some sort of abbreviated word that I could not understand or distinguish, and was constantly getting confused.

"Around this 'ticker' gathered and grouped a knot of eager, nervous, and anxious men. Ten, fifteen, or twenty at a time would clutch at the tape, as it streamed out with its endless lines of quotations, and mutter to themselves, jabber at each other, swear like pirates, drop the tape, and dash away. Others would dart in, clutch the tape, swear or chuckle as their fortunes went, wheel about, give orders to their broker to buy or sell, as they prophesied the future of the market; and so it went on all day from 10 till 3, when the battle was ended by the fall of the hammer in the Stock Exchange.

respond with the varying lengths of the telegraphic characters, and thus a uniform space is ensured between the successive characters, however greatly their respective lengths may vary. Many experiments were made, in connection with this perforator, with the Bain system of transmission, which had been somewhat modified and improved by Humaston, on the lines of the American Telegraph Company from 1861 to 1866, in which a speed of 100 to 120 words per minute was attained upon ordinary circuits, but the system was never brought into actual service.

22

Ace. 11. 78

Autographic Telegraphy.—Autographic telegraphy or the process of transmitting messages in the actual handwriting of the sender, has occasionally during the past 30 years constituted the special study of scientific minds. So long since as 1850 Mr. F. C. Bakewell invented a copying telegraph by means of which autographic telegraphy was effected, and this was probably the first time it was effectually accomplished. In this instance the message was written by the sender with a gummy ink or varnish on metallic paper or tin foil, and this writing was by the aid of mechanism used to actuate electric currents in such a way as to produce a record at the distant station by the chemical decomposition of a solution with which the receiving paper was damped. Both the written message and the paper were fixed around cylinders of similar form and dimensions, one being placed in the transmitting and the other in the recording instrument, and the cylinders were caused to revolve with corresponding velocities. Each time the gummy, and consequently raised, lines of the writing were crossed by a pointer under which the metallic paper was traversed in the transmitter, a mark corresponding in position was made on the prepared paper at the receiving end. It therefore followed that the sum of all the marks reproduced the writing itself. Mr. Bakewell successfully reproduced the writing in white on a blue ground, but the process failed to become one of public utility owing to the extreme slowness with which the apparatus worked and the difficulty that was experienced in maintaining uniform and synchronous motion in the instruments. In 1856, the Abbé Caselli, in Italy, endeavoured to solve the problem of autographic telegraphy in a similar manner. His apparatus was exhibited in England, and it was used practically between Paris and Marseilles and Paris and Lyons. Plans, drawings and autographic sketches were faithfully reproduced at distant places, but it was found that the apparatus had not only the defects of Bakewell's but it was very costly and complicated. Two other subsequent workers in this direction were M. Meyer and M. Lenoir, who tried to accomplish the same results with ordinary ink. They, however, pursued their investigations quite independently of and unknown to each other. We have recently been afforded the opportunity of examining the latest example of this class of apparatus at the General Post Office, where it has been submitted to the authorities for trial. This is the invention of M. d'Arlincourt, of Paris, and its general principles are similar to those which govern Bakewell's system. The distinguishing feature in D'Arlincourt's apparatus, however, is the introduction of an extremely ingenious synchronous movement, by means of which the speed of travel of the cylinders is rendered uniform, both in the transmitting and the recording machine. The message to be sent, which may be either in the ordinary hand or shorthand, is written with a thick gummy ink upon a strip of metallic-faced paper about 12 inches long and 2½ inches deep, which is wrapped around the cylinder of the transmitting instrument. A strip of white paper chemically prepared and of similar dimensions is placed on the cylinder of the recording apparatus, and the instruments are placed in electrical connection and started. The raised writing, actuating the electric current, causes a reproduction of the original message in *fac-simile* on the paper in the recording instrument, which may be hundreds of miles away from the other. Upon the occasion of our visit the two instruments, although in the same room, were practically placed 200 miles apart. The writing can be reproduced in either blue, brown, red, or black, according to the chemical preparation of the paper, but always on a white ground, and a number of copies can be taken from one original. In the same way, sketches, plans, or drawings may be faithfully transmitted; some sketches were, in fact, accurately reproduced on the occasion of our visit. Although the apparatus is perfect in its action, it still has one drawback, which was common to its predecessors—that of slowness of reproduction. The time occupied in revolving the cylinder a sufficient number of times to allow the pointer to traverse the whole surface of the paper is seven minutes, and this rate of speed is far below that required and attained in practice for commercial purposes. The Post Office authorities, to whom we are indebted for our inspection, do not, therefore, see their way to utilise M. d'Arlincourt's ingenious invention at present. It is, however, being worked in France in fortresses and for similar military purposes for use in which and in some special cases it is exceedingly well adapted.—*The Times.*

The Magnet - Sept. 15 - 1880

NOVEL SYSTEM OF TELEGRAPHY

An afternoon paper a few days ago printed the following article, which will be read with interest:

Royal E. House, the last of the original telegraphers of the Morse time, thirty years ago, proposes to revolutionize telegraphy, and may do it before he dies. He is an old man, although the youngest of the leaders in the days when "far writing," which has become a fact, was regarded as a myth. He has perfected a system by which from 250 to 300 words a minute can be transmitted, received, and permanently recorded, and which is automatic. The new designs are the perfection of the old House ivory-keyed, automatic instrument of thirty years ago, and are the result of twelve years of unremitting labor. In a sentence, it is intended to make cams, cogs, levers, and electricity do the work of brains, hands, and experience; to send messages with the enormous rapidity of mechanism; to have them received and recorded automatically and without the necessary presence of an operator; to make money for the capitalized companies and to save it to individuals. If successful, it is the cheap postal telegraph system in a nutshell. The inventor calculates—and figures seldom lie—that messages can be sent by the new system at something less than one-tenth of their cost by the present improved Morse system, allowing for power, machinery, batteries, paper, and the salaries of operators and other employes.

There are four machines, or instruments, which constitute the system. Each one of them would be useless without the others. The first is built on the general principle of the type-writing machine, but instead of printing characters cuts slits of greater or less length in an interminable strip of hard and stiff Manilla paper, with pointed knives which are raised alternately through the lower and upper edges of the paper by a system of levers worked by a series of brass keys, the strip of paper passing from a wheel through a narrow brass galley and under constant pressure over the little slots through which the knives work. Foot, hand, water, or steam power may be used in running the machine, and an expert operator can strike from 150 to 200 letters per minute. The length of the slit indicates the letter to a small fraction of an inch.

This strip of paper, whose marks are not those of a punch, but cut slits in a rapidly moving strip, is then placed in a machine connected with a battery, and moves quickly through it. Two constantly revolving wheels, with sharp but not keen edges, fall readily into the slits—upper and lower alternately—of the paper, and thereby make an electrical connection with a receiving instrument at another office, with a set of knives similar to those in which the original slip is placed. The knives in the second machine cut slits of a length corresponding to those in the original, and can be read by an expert, although they can be printed in the fourth machine with such rapidity as to make handwriting comparatively tedious and useless. This last instrument prints on somewhat the same principle as the gold and stock automatic telegraph, but the letters are printed from the cut slip without any other interference than that of the power by which the machine is run.

These messages record themselves, and the presence or absence of an operator at the receiving end is of no consequence. They can be sent with all the rapidity of which perfect mechanism is capable, and will, it is claimed, average 200 to 250 words per minute, or approximate 15,000 words per hour of constant work. All delay will be in preparing instruments, and the work then can be accomplished by operators at such times as the wires are occupied from other stations.

Perhaps the most remarkable feature of the system, and the one which will strike operators and electricians as the most improbable, is the simplest. It is that all messages can be sent to any particular station and to no other, and without being heard or repeated at any other. The "call" is so arranged in its automatic way that while the machinery is in movement in every office, the knife-like wheel only fills the call slits on the tape in the office for which it is intended, giving an automatic reply, and the similarly moving wheels in every other office, failing to fit the slits, have no impression.

which the paper is rapidly whisked by turning a revolving handle. The turning of this handle is therefore all that the operator requires to do in the act of sending a message.

The distinguishing feature of the rapid telegraph, and the source of its high speed, is the absence of spaces between each signal current composing a letter. In the old system, as is well known, each signal current of a letter or "dot" and "dash," is separated from its next neighbour by a space; and, of course, much time is lost in transmitting these gaps. In the new system the spaces are avoided by causing the receiver to mark the successive signals of the letter at opposite sides of the axis of the moving paper. Thus by the simple device of placing the signals in double file, the time lost in separating them by longitudinal spaces when placed in single file is saved, for the end of one signal may coincide in point of time with the beginning of the next, although the signals are rendered quite distinct by their side-by-side position. This arrangement will be best understood by a reference to the following diagram, which represents a portion of a message as received with the corresponding punched slip beneath.

FIG. 1.

FIG. 2.

The signals themselves are dots and dashes, the latter being shorter than is usually the custom, and the space between each two *letters* is marked by a longer dash.

The transmission of the signal currents is effected by employing two batteries, one having its copper pole to line, and the other its zinc pole. The double row of holes in the punched paper transmit alternate currents from these two batteries into the line by means of the two spring points, which make contact with the metal pulley over which the paper passes whenever a perforation in the paper allows them to do so. For this purpose the pulley is made double, so that there is one point to each distinct half of the wheel. When it is known that each half of the wheel is connected to its own battery, and that both the points are connected to the line, the course of the current will be readily understood.

The marking of the message is effected in the receiver by a modification of Bain's electro-chemical process. The currents pass from the line to a pair of pointed steel styluses, which rest side by side upon a travelling slip of paper, which has been impregnated with a solution of equal parts of nitrate of ammonia and ferrocyanide of potassium. From these styluses they pass through the paper to a metal pulley beneath, and thence to earth. In passing through the prepared paper, the currents decompose the chemical solution with which it is moistened, and stain the track of the styluses with a succession of dots and dashes, the shorter currents marking dots, and the longer ones dashes. The blue stains are due to the formation of Prussian blue.

The American rapid telegraph is the invention of Messrs. Theodore M. Foote, C. A. Randell, and Frank Anderson, and was first put into practical operation on the 19th July last between Boston and New York. The ordinary rate of working over this line, a distance of 250 miles, is 1000 words per minute, but the apparatus can readily work up to 1800 words per minute. The American Rapid Telegraph Company is succeeding so well with it that, though they began business so recently, they will soon possess their own lines from New York to Washington, Cincinnati, and Chicago.

A practical trial of the apparatus has been made on some of the longer English lines by Mr. W. H. Preece; but the induction which is so strong on our lines has reduced the speed of working considerably, and lengthened out the signals by its retarding effect. In fact it has not proved so rapid as the Wheatstone system now employed by the Government electricians, and in the mean time the use of the apparatus is in abeyance. On the American line there is little or no induction, owing to the fact that it has been as yet operated along a line carrying only one wire; but the inventors hope yet to improve its speed on English lines. The apparatus shown at the Society of Telegraph Engineers has, we believe, been taken over to Paris, in order to try it on the Submarine Company's line from Paris to London.

Engineer Oct. 15. 1880 23

Engineer Oct 15 1880

A New Telegraph Machine.—Mr. Royal E. House, the last of the original telegraphers of the Morse time thirty years ago, has, it is said, perfected a system by which from 250 to 300 words a minute can be transmitted, received and permanently recorded, and which is automatic. The first is built on the general principle of the type-writing machine, but instead of printing characters cuts long slits of greater or less length in some strip of hard and stiff Manilla paper, with pointed knives, which are raised alternately through the lower and upper edges of the paper by a system of levers worked by a series of brass keys, the strip of paper passing from a wheel through a narrow brass galley and under a constant pressure over the little slots through which the knives work. The length of the slit indicates the letter to a small fraction of an inch. The strip of paper, whose marks are not those of a punch, but cut slits in a rapidly moving strip, is then placed in a machine connected with a battery, and moves quickly through it. Two constantly revolving wheels with sharp but not keen edges fall readily into the slits—upper and lower alternately—of the paper, and thereby make an electrical connection with a receiving instrument at another office, with a set of knives similar to those in which the original slip is placed. The knives in the second machine cut slips of a length corresponding to those in the original and can be read by an expert, although they can be printed in the fourth machine with such rapidity as to make handwriting comparatively tedious and useless. This last instrument prints on somewhat the same principles as the gold and stock automatic telegraph, but the letters are printed from the cut slip without any interference than that of the power, by which the machine is run. These messages record themselves, and the presence or absence of an operator at the receiving end is of no consequence. They can be sent with all the rapidity of which perfect mechanism is capable, and will, it is claimed, average 200 to 250 words per minute, or approximate 15,000 words per hour of constant work. All delay will be in preparing the instruments, and the work then can be accomplished by operators at such times as the wires are occupied from other stations. Perhaps the most remarkable feature of the system and the one which will strike operators and electricians as the most improbable is the simplest. It is that all messages can be sent to any particular station and to no other, and without being heard or repeated at any other. The "call" is so arranged in its automatic way that while the machinery is in movement in every office, the knife-like wheel only fills the call slits on the tape in the office for which it is intended, giving an automatic reply, and the similarly moving wheels in every other office, failing to fit the slits, have no impression. 28

28

THE AMERICAN FAST SPEED AUTOMATIC TELEGRAPH.

SOME trials have recently been made on the Postal Telegraph wires of a fast speed automatic telegraph system, the invention of Mr. T. M. Foote, of Brooklyn, and F. Anderson, of Peekskill, America. Although on the longest circuits the system failed to attain the speed given by the Wheatstone instruments, yet on short circuits very high results were given, and the system therefore merits a description.

As in the Wheatstone instrument, the currents in the transmitting portion of the apparatus are controlled by a perforated slip of paper; the latter is shown by fig. 1.

A peculiarity in the system consists in the fact that each signal is formed by either one positive or one negative current, and that two currents of a like sign never immediately follow one another—that is to say, a positive current always follows a negative, and a negative a positive current.

The perforated slip is passed over a metallic roller, W (figs. 2 and 3), which is divided into two insulated halves, which are respectively connected to the zinc and copper poles of a split battery earthed in the middle. Two brushes, *b*, *b*[1], both connected to line, press on the two halves of the rollers and make contact with one or other half as they drop through the perforations in the paper slip when the latter is moved over the roller.

At the receiving end of the line a chemically prepared paper (as in the Bain system) passes under two metallic styles which press on the roller, W; one style being connected to line and the other to earth, as shown in fig. 3. According, therefore, as a positive or a negative current flows to line a mark is made on the upper surface of the paper by one style or the other.

Let us now suppose the slip represented by fig. 1 is turned round and passed from left to right over the roller, W, and under the brushes, *b*, *b*[1], then the brush, *b*, first drops through the first perforation and sends a short zinc current, which represents the first dot of the letter A. The brush, *b*[1], next drops through the first of the two perforations on the upper edge of the slip, fig. 1, and sends a short copper current to line, which is immediately followed by a second short copper current from the brush, *b*[1], making contact through the second per-

25

foration; two dots close together are thus formed, but the condenser, C (fig. 3), being charged by the current, discharges itself when the brush is passing over the small interval between the two dots, and this discharge current at the receiving end practically turns the two dots into a dash.

Inasmuch as the dash is not formed by a current left on for a lengthened period, but by two successive currents filled up between, as it were, the condition of the line when the brush leaves the second perforation is the same as it would be if the brush had only passed over a single perforation; thus, after a dash has been formed the line is perfectly clear to receive another signal. After the letter has been completed a dash formed by four perforations close together is produced, which spaces the letter from the succeeding letter.

Now, supposing that it were required to signal two letter A's one after the other, then if we look at the left-hand end of the perforated slip, fig. 1, we can see that if the relative positions of the dot and dash perforations were the same in both cases two distinct signals would have to be formed by similar currents immediately following one another, thus we should have two A's formed as follows:— . ˙˙ . . . . . ˙˙ If, however, we wish positive and negative currents to succeed one another alternately, we should require to have the perforations arranged as follows, . ˙˙ . . . . ˙ . .; in other words, we require to have the position of the perforations representing the second letter A reversed. Now, if all the letters were formed by an *odd* number of signals the reversals of the currents would always take place correctly, but inasmuch as some letters are formed by an even number of signals and some by an odd number, it would be necessary that the perforations representing these letters be reversed continually. The mechanism by which this end is effected is highly ingenious and effectual, though complicated. The perforations are made and arranged by means of mechanism actuated by a key-board similar to that of a Hughes type printer.

Although the system has not been entirely successful in this country, in America it has been worked to a speed of 1,500 words a minute, but this has been obtained with a circuit on an independent line of poles, and with a wire of a large gauge.

The Wheatstone apparatus in England, up to the present, has by no means been worked up to its greatest possible capacity; in fact, no attempts have been made to obtain a greater speed than 250 words a minute. With greater driving power and lighter moving parts a greatly increased speed is undoubtedly possible. The great advantage of the Wheatstone apparatus lies in the fact that in the transmitter, signals cannot be missed—that is to say, the perforated slip cannot move forward to cause a second contact until the mechanical action causing the first contact to be made has acted properly. Where a brush is used to make contacts there is a tendency for the former to jump across from one side of a perforation to the other, instead of dropping down between and making a firm contact.

Electric Signals for Railroads—Successful Operation of the Union Electric Signal Company's Apparatus.

The electric signal for railroads is no new invention, but of late it has been greatly improved. The improvements in the Union electric signal over any other safety signal yet adopted were shown yesterday upon the section of the Eastern road, below Salem, where it is now in use. It seems to be especially valuable from its extreme simplicity, and the more important fact that but one wire is used, thus making it safer, more reliable and less expensive. It only requires a single cell of the gravity battery to operate all the signals reliably through a mile section of track, and this arrangement may enable almost any road to place the cell in a switchman's house so that there can be possibly no danger of freezing in the coldest weather. The rails being connected by a wire fastened to a pin and firmly driven into the rail a few inches from the joint, makes a perfect and constant rail circuit system, and any breakage of the current, by moving a switch, breaking of a rail or laying a rail across the track, will instantly set the danger-signal and prevent derailment or collision. There is also an overlapping system, by which the train, as it enters a section, sets the danger signal in front of the engineer, so that he may know that it is in operation. After passing on to the third section, at least 1,400 feet, the engine reaches a relay signal that at once releases the first danger signal, thus practically keeping one whole section behind unoccupied, and if by any cause a car breaks away and remains standing upon a section, the danger signal remains set behind, so that it is impossible for a collision to occur. The usual attachments of crossing, warning and station bells are used. By this arrangement the bell rings when the train enters the section, and stops ringing when it stops at the station. To these admirable arrangements for safety can be added an interlocking switch system that would seem sure to prevent collisions no matter whether the switchman was forgetful or whether the switch was criminally tampered with. By an ingenious and at the same time plain and practical piece of mechanism, the switch is so locked that when a train is upon the section moving in either direction the switch bar remains immovable; even the destruction of the entire switch frame will not release the bar so that the rails can be moved out of position. When the switch is changed a distant danger signal is set, as also when a draw is opened, and by a little repeater in the switch-house the man in charge knows that that distant signal is operating and he is protected. These are among the most important features of this new system of electric signals, and, devoid of all technical terms, the whole system resolves itself into what may be called a perfect constant circuit system, easily and cheaply maintained, furnishing in all weather a full flow of electricity with a sufficient reserve force for unusual demands, and at the same time, when from any cause whatever the circuit is broken, a danger signal is at once set and remains set until the circuit is closed. This system can be managed by hand also. It has been tested and is now in use on the Fitchburg, Old Colony, Pennsylvania Central, Michigan Central, Chicago, Burlington and Quincy and other western roads, and everywhere gives perfect satisfaction, as it works just as well in snow and ice as in the heat of summer. A party consisting of some newspaper men, President Phillips of the Eastern road and some of his subordinates; J. Gardner Sanderson, general manager of the signal company, Oscar Gassett, superintendent; Mr. Bates, foreman, and several railroad men yesterday rode to the section between Salem and Beverly, witnessed the practical operation of the signal, and examined the system carefully. Upon the return trip a visit was made to the Eastern railroad car-shops at Salem, and upon reaching Boston, the shop of the signal company was visited, and a model of the whole mechanism was inspected.—*The Boston Daily Globe.*

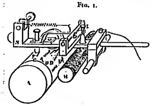
MEYER'S AUTOGRAPHIC APPARATUS.

Caselli, the abbot, was the first to reproduce at a distance, by telegraph, the exact facsimile of the despatched message. His electro-chemical instrument, used for many years in France, was on view at the 1867 Universal French Exhibition.

About that date M. Meyer, without recourse to chemical decomposition, succeeded in reproducing the facsimile in ink upon ordinary paper. His apparatus greatly simplified Caselli's, which it substituted from the year 1868. Its description is as follows:—Upon a brass or wooden table is placed a clockwork movement. On one side of it are a cylinder and slider, mediums for transmission; on the other side are the spiral cylinder and endless paper for the reception of messages. The motor is a weight, and the motion is regulated by the vibrating pendulous stem whose function is to establish a regular and synchronical action between the sending and receiving stations. There are therefore three portions to describe, viz., the transmitter, the receiver, and the synchronism system.

The Transmitter.—The sender writes his message with an insulating ink upon a certain limited surface of metallic paper, sometimes as large as 1 decimetre, but more generally for the public, 30 square centimetres. As to the metal-paper, it is the usual tin or silver paper of commerce. The despatch, design, or whatever may be on the paper, is wound round the cylinder A, which is 1 decimetre in circumference, and turns with a speed of 75 revolutions a minute. Upon a support, parallel to the cylinder's axis, slides the slider, furnished with the stylo, or platinum point, c. I is a screw whose point

Fig. 1.



enters into the thread of the endless screw H, which in turning moves the slider from right to left. When the cylinder A makes one revolution the slider advances ¼ of a millimetre and the stylo c describes a complete helical turn. The cylinder continuing to revolve, the stylo performs upon its circumference a helical line whose spirals are distant ¼ of a millimetre from each other. Now, as the message to be transmitted occupies the surface of the cylinder, all the points* of the message are successively in contact with the style, which, in its course, alternately touches an inked and a metallic surface in an irregular order, according to the contents of the message. The current passes during the passage of the stylo over the metallic-paper surface; it is interrupted on the insulated ink part, and it is this succession of makes and breaks which

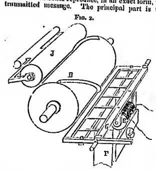
* Excepting a very fine spiral line, ¼ m.m., or nearly 1-tenth of an inch, broad.

constitutes the autographic transmission. The current from the battery divides in the sending portion of the instrument into two branches; the one by the line wire, and the other to earth through the slider and the brush, D, which rubs against the metallic sheet of the message.

The result of this arrangement is that the battery always works, and it is the position of the stylo c which determines the distribution of the current by one or the other circuit. When it rests upon the metal the local circuit is closed; all the current goes to earth through the style, the metallic surface, and the brush; and the line—on account of its great resistance—receives only a branch current which may be neglected. On the contrary, when the stylo passes over the inked portion, the local circuit is interrupted, and the whole battery charge goes to line. There is therefore an emission of the current on the line every time that the stylo passes over the writing, and a breakage of the current or discharge to earth every time the stylo touches the metal-paper.

The Receiver.—We now shall describe how these successive currents reproduce, in an exact form, the transmitted message. The principal part is the

Fig. 2.



helix B—a cylinder having upon its surface a metallic helical band, 1 decimetre in length, and embracing the whole of the circumference. Above it a roller, saturated with an oily ink, freely revolves, and moistens the projecting band of the helix. Below it is placed a lever, G, in the form of a printer's frame or chase. The edge of this chase, during its oscillations, strikes against the inked band of the spiral. In order to receive the printings an endless band of paper is made to unroll around this edge. The paper follows the movements of the chase. It is 1 decimetre in size, and the width of the cylinder B. The paper band, pressed between two revolving cylinders, unrolls itself ¼ m.m. per turn of B. It has been shown that the stylo advances the same quantity for each revolution of the cylinder. Consequently the surface of the paper band run out in a given time is the same as the surface traversed in the same time by the stylo. When the cylinder B makes one turn its band traces upon the paper a straight transverse line in ink, which is repeated for each turn. These successive transverse lines, distant from each other ¼ m.m., for all purposes touch and form upon the band of white paper a blue ground. Thus the cylinder B is the writing medium of the apparatus. At the lower part of the lever G is screwed E, a small straight electro-magnet, whose soft iron bar serves for an armature to F—a permanent horse-shoe magnet. When the coil is traversed by a current the extremities of the core take the same polarities as the poles of the permanent magnet, and the lever G is then repulsed. The edge of the chase quits contact with the cylinder, and some white appears on the paper,—in size according to the length of time the current traverses the coil of the electro-magnet E. On the cessation of the current the core of the magnet E is attracted by the permanent magnet F, and the paper is again pressed against the cylinder.

We have previously described how, at each passage of the stylo on the ink, the battery current flows to line. This current works a relay at the receiving station.

Now the cylinders A and B perform their revolutions in the same time. The slider c describes then as many spirals upon the cylinder A, and equally spaced, as the cylinder B traces parallel dashes. Thanks to the synchronic movement which animates the two apparatus, the course of the slider rigorously coincides with the rotation of B, and when the stylo is found at the commencement, in the middle, or two-thirds of the circumference of the cylinder A, B presents to the surface of the paper a point at the commencement, or in the middle, or two-thirds, of the paper band in the direction of its breadth. Consequently all the inked parts which meet the style during the first revolution are interpreted, at the receiving end, by dashes corresponding in length with the duration of the passage of the stylo over the ink. The same takes place for all succeeding turns.

The success of the invention depends on the mechanism by which the movements of the instruments at the receiving and sending stations are controlled. The regularity, as before mentioned, is obtained by the use of a conic pendulum, which is a stem supporting a ball of a certain weight. When two pendulums thus constructed are set in motion to the same pitch, they describe sensible isochronous amplitudes, maintaining the concordance of the two apparatus for several minutes—a time sufficient to traverse the whole of the cylinder.

8

FAC-SIMILE TELEGRAPHY. July '76

THE one thing wanted in telegraphy by which a message may be practically transmitted over a wire and appear at the distant terminus in the *exact handwriting of the sender*, has at last been accomplished by an American electrician, Mr. W. E. Sawyer. The field opened to the telegraphic world by this invention is almost without limit.

The instruments are wonderfully simple in construction and easily comprehended.

The system is capable of transmitting over a single wire from 50 to 150 words per minute, against a possible 30 to 40 by the Morse system, which is that now in common use. But by this system a person's own handwriting is transmitted by telegraph the same as though sent by mail, and, in brief, simply accomplishes letter writing by telegraph. In order to render its operation fully understood it may be described as follows:

First, the sender of a message writes it upon ordinary white paper; the written message is then laid upon a metallic plate and passed between two rollers, with the effect of transferring the copy to the plate, which may be done any time within ten hours after writing. Then the plate containing the copy is placed upon a semi-cylindrical holder which traverses a little track, and the instrument is set in motion, the whole operation up to this point having been accomplished in less time than it takes to write it; whereas, by the Morse system, quite a number of minutes elapse before the message reaches the operator. The metallic plate is a conductor of electricity, while the lines of writing are non-conductors. Over the cylindrical plate are carried metallic points upon revolving arms; whenever the point is upon the metallic surface, the electric current passes through to the wire; the instant the point touches a line of writing, the connection is broken and a dot is made upon chemically prepared paper, placed upon a similar instrument at the receiving point. The two instruments operate synchronously—*i.e.*, the moment a point is passing over the surface of one instrument, it is followed exactly by the point on the other instrument. An ingenious mechanical arrangement perfects the transmitting powers and prevents the possibility of one instrument gaining over the other. At the same time the points are moving over its surface, the plate is moved slowly horizontally, so that the entire surface is traversed. The transferred message is, of course, in reverse, but is brought straight by running the receiving instrument in an opposite direction. Each instrument is fitted to either receive or transmit, at pleasure. The rate of speed varies according to the closeness of the writing; the points traversing the entire surface of the copy, it is immaterial as to the number of words, only the space they occupy requiring a given time to be gone over. Ordinary writing will be transmitted at the rate of from 50 to 100 words per minute.

The message, as received, is ready at once for delivery, and appears in close, dark blue dotted lines, on white paper. There is no loss of time in counting the words at the sending station, as is now the case, nor delay in getting to the hand of the operator; but, in a quarter of a minute's time from its being received, it is silently speeding its way to its destination, and automatically preparing itself for delivery. The wonderful facilities of the system render it peculiarly adapted to a large and hurried business. It is the fruit of many years' close application, hence the perfection with which it makes its appearance.

The writer of a message is, of course, as usual, supplied with blanks. In the system proposed—and which is now being perfected by the company already formed to utilize this great invention—for whatever may be written upon the blank he will pay an invariable sum of money, if under 250 miles; if over, double that amount in stamps, to be furnished by the company, and used the same as postage stamps. Whatever is written upon the blank, whether five words or fifty, will be sent for the same amount. It is so much blank passing through the instruments, and no cognizance is taken of its contents.

A company called "The United States Postal Telegraph Company" has been incorporated under the laws of the State of New-York for the purpose of constructing lines and operating under the letters-patent granted to Mr. Sawyer. President, John H. Cecil, of New-York; Vice-President, A. M. Allerton, of New-York; Secretary, George H. Williamson, of New-York; Treasurer, C. A. Kittle, of New-York; General Superintendent, James G. Smith, of Hackensack, N. J.; Electrician, W. E. Sawyer, of New-York. They will start with a capital stock of $2,000,000, which is to be increased to $10,000,000, as the extension of the lines may require.—*Boston Journal of Commerce.*

2351. TELEGRAPHIC CIRCUITS, *A. M. Clark, Chancery-lane.—Dated 28th June, 1875.*

This invention is more especially designed to be applied to *fac simile* or autographic telegraphs, for which the inventor obtained former letters patent; but it is obvious that they may be applied to most other telegraphs, such, for instance, as the Morse and the automatic. The main principle consists in a division of the transmitting battery current, and the placing of that battery at the receiving end of a line.

TELEGRAPHIC FAC-SIMILE TAPE. Jan 77

L. YOUNG, of New York city, has invented a new tape, as follows:

Instead of paper, I use a strip of tin-foil, or other metallic surface, made smooth, and washed over with varnish of bees-wax, or other non-conducting substances. Upon this prepared tin-foil or smooth metallic surface, washed over with a non-conducting substance, the message is written with a fluid composed of colored caustic soda. After the message is written, a wet sponge easily washes away the varnish from the letters or message, leaving the writing metallic on a non-conducting surface of varnish. The tin-foil or metallic plate is in communication with one pole of the battery or instrument; the opposite pole of the battery passes over the surface of the tin-foil or metallic plate in the shape of a steel point, or a number of points passing over the plate or foil covered or washed with the non-conducting varnish. The electrical current or connection is broken; but in passing over the letters or symbols written on the plate or tin-foil the current is instantly connected. This connection is instantly indicated on the receiving-instrument by blue marks on a prepared paper soaked in prussiate of potassa, transmitting the exact shape or form of the written characters or symbols. Any caustic alkali may be used as the writing fluid.

ELECTRIC ENGRAVING MACHINE.

We may here mention another and more important modification of Caselli's invention than that of M. D'Arlingcourt—more important, at any rate, when considered, as we ought to consider every phase of scientific progress, in its connection with the wants of everyday life. We did not see this instrument at work at the Exhibition, nor is it altogether new. Several of the machines we refer to were shown at work at a scientific *soirée* at the Conservatoire des Arts et Métiers. These machines would be expensive additions to the workshop, unless a large number of copies of one design was required. The electro-magnetic engraving machine will be easily understood from the previous description. Instead of a cylinder covered with tinfoil, a large cylinder, having a circumference equal in surface area to the

FIG. 4.

FIG 3

utensil to be engraved, is used. The design to be reproduced is carefully inlaid in brass upon the surface of the cylinder. A good conducting material is used to make the cylinder. An electro-magnet at the working end acts or does not act upon the graving tool, allowing it to cut or not as the current passes through what may not inappropriately be termed the line wire, which contains the electro-magnet, or a short circuit. Whenever the point touching the revolving cylinder comes into contact with the brass, the graving tool is withdrawn, and ultimately the whole surface, except that represented by the brass design, is cut, and the design stands out in relief on the tray or on the other object worked. A little ingenuity spent on the machine would make it work quite automatically, so that one man could look after several of the machines; in fact, we see no great difficulty in connecting several graving tools with one cylinder, and thus reproducing the design three or four times at once.

9

8 10

11

D'ARLINCOURT'S AUTOGRAPHIC TELEGRAPH.

In the number of the Journal for Dec. 15th we gave some illustrations of results obtained by means of this ingenious form of telegraph instrument. We now give some details of the arrangements by which the apparatus is worked.

The general principle of the system is similar to that of the copying telegraph of Bakewell. The principle of this latter instrument is as follows:—

The apparatus at the transmitting and receiving stations are similar; at each there is a metallic drum, which is caused to rotate at a uniform rate of speed by clockwork mechanism. A toothed wheel fixed to one end of the cylinder gears into a pinion fixed on an axis which runs parallel with the axis of the cylinder, and which has a fine screw thread cut on it from end to end; a nut works on this screw, and has attached to it an arm with a metal style at the end, which presses against the surface of the drum. It is evident that the continuous rotation of the drum will cause the style to be carried along parallel to the axis of the former, and consequently to trace a continuous spiral line on the surface of the drum. Similar forms of apparatus being at the two stations, the drums are connected to the ends of the line wire, the style at the transmitting station being connected to the

positive pole of a battery, whose other pole is to earth; and at the receiving station the style is connected to earth.

At the sending station, the message or design to be transmitted is written on tin foil with an insulating ink, and wrapped round the drum, whilst at the receiving station a sheet of paper wetted with a chemical solution, as in the Bain apparatus, is placed on the drum. As the two drums are caused by mechanism to rotate synchronously, and as the styles at any period of the revolution must therefore have the same relative positions on the tin foil and chemically prepared paper, and further since the current will only flow and decompose the solution during the time the style touches the tin foil, it is evident that the successive makes and breaks of the current will cause successive decompositions of the solution on the prepared paper, and thereby produce, by a succession of broken lines, a facsimile of the design or writing traced on the tin foil, the design appearing in white, and the ground in a colour corresponding to the nature of the chemical solution used. This, if the latter be ferrocyanide of potassium, the ground work will be of a blue colour. The success of the arrangement obviously depends upon the absolute synchronism of the revolution of the two drums, and this, in the apparatus subsequently invented by Caselli, was attained by means of electric pendulums; the arrangement, although successful, being somewhat complicated. A point of novelty in the latter system consisted in causing the style, whilst pressing on the portions of the metallic paper, to short circuit the battery, so that a current only flowed to line when the style passed over the insulating ink. This caused the facsimile on the chemically prepared paper to appear in colour, whilst the ground remained white. Instead of using the rotating drum, the style was caused to traverse backwards and forwards over the surface of the paper.

M. D'Arlincourt in his system employs the rotating drums and traversing style of the Bakewell instrument, and the battery short circuiting method, adopted in the Caselli instrument, but his mechanism for synchronizing the revolution of the two drums is a noticeable point in the invention. Fig. 1 shows generally the principle of the apparatus. *a*, *a'*, are drums provided with styles *s*, *s'*, as in the Bakewell apparatus. Ebonite pieces, *b*, *b'*, flush with the surface and running the full length of the drums, are fixed to the latter, so that when the styles rest on them the latter are insulated. *m*, *m'*, are electro-magnets, which have their armatures normally attracted by means of permanent magnets attached to their cores, as in the Hughes' type printer. The arms of these electro-magnets, when normally attracted, arrest the rotation of the drums when the latter are in the position shewn in the figure. *c*, *c'*, are cams fixed to the axes of the drums, and which have each a projection and a depression, the former of which raise the levers 2, 2', to the positions indicated in the figure, and which cause them to be in contact with studs 1, 1'. The depressions in the cams when the drums commence to rotate, allow the levers to change to the positions where they make contact with the studs 3, 3'. Finally when the drums rotate further, so that the levers press against the continuous surfaces of the cams, their position will be such that they make contact with the studs 2, 2'. *f*, *f'* are levers actuated by the same clockwork which rotates the drums, and which replace the levers *n*, *n'*, on to the cores of the magnets *m*, *m'*, after the drum has fairly commenced to rotate, when released by a current sent through *m* or *m'* as the case may be.

The clockworks which rotate the drums are so arranged that one drum can be caused to rotate at a rate one tenth less than the other. This is accomplished by the device shown in fig. 2.

a, *b*, are two crown wheels, which can slide along, but be rotated by the axle *f f*, which axle is geared indirectly to the drum on which the style presses. *c*, *d*, are two wheels on the axis *g*, which is connected to the speed regulator, which latter can only rotate at a certain definite velocity. In the position shown in the fig., wheels *a* and *d* gear together, but if the crown wheels are shifted to the left, the wheel *b* gears with wheel *c*. Since the relative sizes of the wheels are such that when *a* gears with *d*, the rate of revolution of *f* with *g*, is one-tenth less than it is when *b* gears with *c*, and since *g* at both stations can only rotate at one definite speed, therefore if at one station *a* gears with *d*, and at the other, *b* gears with *c*, then one drum will rotate with a velocity one-tenth less than the other. A small wheel *w* is attached to a spring fixed to the tubular axis on which *a* and *b* are mounted, for the purpose of keeping the wheels firmly in either position to which they may be shifted.

The working of the apparatus may now be made clear:—Supposing B to be the transmitting, and A the receiving station, then the metallic surfaced paper, on which the design or writing is traced, is put on drum *a'*, and the chemically prepared paper on drum *a*. The papers are so wrapped round the cylinder that they cover the whole surface, except the ebonite portions. The clockworks are so geared that *a'* rotates faster than *a*; also by means of a switch, 2' and 3', are connected together. The clockwork at A is now started by throwing *n* permanently out of gear, and drum *a* commences to rotate; as it does so, lever 2' drops from the projection into the depression in the cam and makes contact with 3, this causes a current to pass out to station B where it enters by lever 2', passing to 1', and through *m'* to earth; lever *n'* is thereby immediately released and rises up under the influence of a spring, thereby allowing drum *a'* to start off; immediately it does so, lever 2' drops down to 3' and then up to 2', where it remains during the remainder of the rotation of the drum; *l* in the meantime has risen to 2, so that even if *n* had been in gear the contact made by 2' with 3' would have produced no effect. The two levers being now at 2 and 2' respectively, the marking currents are duly transmitted between the drums. As *a'* rotates faster than *a*, before the lever 2' is again affected, *a'* will have completed its rotation and have been brought to a stop by *n'*, which, as has previously been explained, has been replaced by *f'*; and lever 2' will again have been brought to the position shown in the figure. Drum *a* then, when it has completed its rotation and continued it, again moves lever 2 to 3, again starts off *a'*, and so on; thus drum *a* rotates uniformly and continuously, whilst drum *a'* rotates also uniformly but a little faster than *a*, and is brought up sharp and started off again at each revolution. Practically then *a'* rotates synchronously with *a'* and being checked at

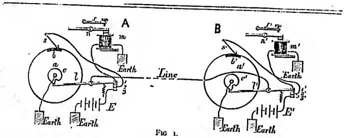


Fig 1.

each revolution can never be more than a tenth of a revolution out, and inasmuch as this one-tenth is distributed over the whole time of the revolution, no appreciable erratic effect is produced in the copy.

As it is very essential that the drum, which is checked at each revolution, should start off with its full velocity when the electro-magnet releases it, the clockwork by which it is turned gears friction tight with it, so that the train continues to run although the drum is stopped, and thus, when the

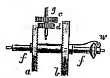

Fig. 2.

latter is released, it at once moves off with the same velocity at which the train is running. As the inertia of a drum, although light, tends to stop the motion of the train, a second train of clockwork quite independent of the first is connected rigidly to the drum, so that the latter is helped to start off quickly.

The motion of the clockwork train that moves continuously is controlled by means of a thick spiral spring governor, like that now employed on the Hughes apparatus. When working long distances a relay is employed, and there are means provided for neutralizing the effect of the static discharge which comes to be felt on long lines, and which would otherwise render the signals highly irregular and prolonged.

Un nouveau télégraphe écrivant

—

Nous lisons dans la *Nature* de Londres et dans l'*Engineering*, l'annonce de la découverte d'un nouveau télégraphe imprimant aussi curieux que le téléphone. Il paraît que l'écriture tracée à une extrémité de la ligne se reproduit instantanément à l'autre extrémité à l'aide d'une plume qui exécute des traits identiques. On dirait, ajoute la *Nature*, que cette plume est tenue par une main invisible.

Ce journal publie même, dans son numéro du 6 février, le *fac-simile* d'un message transmis de la sorte à Brighton et que nous lui empruntons en lui laissant bien entendu toute la responsabilité de ses assertions.

Comme il est facile de le voir, cette dépêche n'est pas fabriquée à l'aide d'une série de points comme celles du télégraphe d'Arlincourt, mais par une ligne continue.

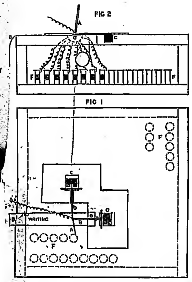
L'inventeur est un mécanicien fort connu de l'autre côté du détroit, qui se nomme M. E.-C. Cowper.

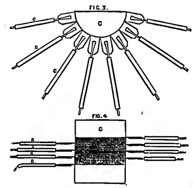
Ce nouvel appareil doit être exposé à la Société des Ingénieurs télégraphistes.

Dans son dernier numéro, la *Nature* n'en fait aucunement mention.

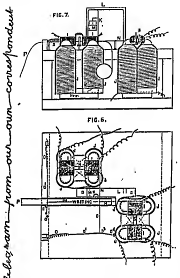
Fac simile d'une ligne écrite à cent kilomètres par l'électricité.

COWPER'S ELECTRIC WRITING APPARATUS.





Telegram from our own correspondent



HORACE must have had in his mind when writing his well-known song, the honest thinker of the present day, who

"Si fractus illabatur orbis
Impavidum ferient ruinæ."

We are becoming so accustomed to hear of new applications of electricity, that we cease to wonder at the increase of the record. If we add to these discoveries, those in acoustic science, and remember the rumours a few years since that an instrument was devised by means of which the voice could be conveyed over many miles of wire and then reproduced; and then this was followed by another instrument that would mock your every sound when spoken to, to be again surpassed by something that would enable the scratch of a brush or the tramp of a fly to be transmitted from one spot to another far away—remembering these successes of the human mind, what can surprise us? The invention before us is worthy of a place amongst the inventions of England, and like all valuable discoveries is remarkable for its exceeding simplicity. The inventor is a well-known engineer, and may, therefore, be presumed to have made a special study of mechanical science. One of the subjects treated at length in almost all text-books is that of the resolution of forces—and it is an application of this law to electricity that has enabled Mr. Cowper to perfect his instrument. We are not aware how the evolution of the apparatus came about, and no doubt Mr. Cowper hardly knows himself, but we feel certain that it might have originated somewhat as follows: Two forces acting upon a body at any angle produce a certain and easily calculated effect upon that body. This calculated effect is generally known as the resultant of the forces. Now if by any means we can obtain constantly varying forces acting upon a body, the effect will as constantly vary. We need enter into no further details as to the resultant effect of such forces—are they not to be found in the satchel of every schoolboy? Mr. Cowper's forces were electrical, his body influenced a pen or stylo, and the motions of his pen are regulated by the variations he gives to his forces. Before describing his apparatus we will roughly show his method of working. Suppose two series of small metallic plates, placed at right angles to each other, and each series connected by means of a line wire to a similar series at a distance. Sliding on the top of a series, suppose a metallic plate large enough to touch two or three or more of the series as it passes over. Each member of the series is to be insulated from its immediate neighbour, and connected to line by wires of different resistance. If now by means of this sliding disc we connect the line to a battery, a current goes from the battery through the disc, through the plates it touches, and through the connecting wires into the line, and the current increases or diminishes according as the disc touches more or less of the plates with less or greater resistance between them and the line. Similarly with the second series of plates and the second line wire. The series at the receiving end being similar to those of the sending end, it will at once be seen that variations of electrical force can be obtained. The two sliding discs can be rigidly connected to a pen, and on motion being given to the pen, motion is given to the discs, and variations of current immediately commence in each line. These variations of current produce variation of force in electro-magnets at the receiving end, and if these electro-magnets act on a body the effect varies. All this Mr. Cowper actually does, and, simple as it now seems, great credit is due to him for having shown us the best way to produce an electro-writing telegraph.

The accompanying illustrations will enable the reader to see exactly how Mr. Cowper attains his object. Fig. 1 is a plan of the sending instrument, Fig. 2 being an elevation of the same. The writer holds the pen, which is rigidly connected to the travelling contacts, and also as shown at a^1 a^2 to the batteries. The slip of paper on which the message is written is moved somewhat in the same way as in a Morse instrument; in fact, the Morse clockwork can be easily used for the purpose. Thus the paper travels under the pen instead of, as in ordinary writing, the pen travelling over the paper. Two sets of thin metal plates *c c* form the contact apparatus, *d d* are the light connecting rods, the ends of which make contact with the plates; *f f* are the resistance coils connected to the contact plates, one coil for each plate, except the first of the series, which is connected direct to line. It will be noticed that the strength of the current entering the line depends upon the plate with which contact is made by the connecting rod. As the rod travels from the first of the series the resistance increases, the current having to pass through $n-1$ resistance coils, as well as the line wire, n being the number of plates from the first of the series to the point at which contact is made. Generally, however, as one contact piece travels from the first of the series, the other travels towards the first of its series, and thus, while the current decreasingly varies in one line, the variation is increasing in the other. A slight knowledge of co-ordinate geometry will enable the student to plot the curve of any letter, and to calculate the variations in the strengths of the currents. Figs. 3 and 4 show respectively an elevation and plan of the thin metal plates, which are insulated the one from the other by paper soaked in paraffin. The receiving instrument, shown in plan and elevation in Figs. 5 and 6, differs from the sending instrument; *h, h*, are light soft iron bars on delicate bearings, having the ends surrounded by the coils *i, i*, to which the bars form a movable core. Through these coils the varying currents of the line are sent, which, of course, have a varying action on the core. *j, j, j, j*, are four permanent or electro-magnets, between the poles of which the coils just named are placed; *k* is a syphon pen. Mr. Cowper prefers, but does not restrict himself to the use of, the well-known syphon pen of Clark. The pen is adjustable from the bridge *l*, and the ink reservoir is shown at *m*. The light connecting rods *n, n*, transmit the motions of the movable cores to the pen; o, o, are springs to enable the pen to resist the pull of the magnets, the connections are shown in o^1, o^2, o^3, the latter being attached to a fixed post o^4.

"As the currents sent through the line wire by the sending instrument vary in strength or power, and cause the light bar of soft iron to move with varying power by its attraction to the stationary magnets; and in order to cause it to take its proper position according to each variation in power, a varying resistance is opposed to it, such as a spring which requires more power to compress it the more it is compressed, that the action of the soft iron bar, combined with that of a precisely similar bar actuated by the second line wire, will cause the position of the pen in the receiving instrument to follow the position of the pen in the hand of the operator at the sending instrument, and thus form the letters. The total strength of the spring or varying resistance can be regulated at will, so that the letters formed by the pen shall be of the same proportionate height and width as the letters written by the operator at the sending instrument. One convenient way of applying the varying resistance to the light bar of soft iron is by placing a very light spring to pull at the end of the bar in the direction of its length, but allowing of the motion of the bar which will thus cause the spring to act with more and more leverage as it moves more out of line with the spring. When so arranged there is required another spring to keep the connection with the pen tight, if such connection is flexible, so that the pen may go backwards as well as forwards over the paper, as the light bar of soft iron moves either one way or the other. But the spring or variable resistance may be made to act both to give the increasing resistance and the power to draw back the pen as well, if the spring is made to pull by a flexible or jointed connection at a fixed point, the line of such pull being parallel, or nearly so, to the light bar of soft iron, while another rigid or flexible connection from the end of the bar to the connection to the spring has the pen attached to it at about the middle of its length, which arrangement will give the same result as the two springs before described.

The accompanying is a specimen of the writing obtained. This specimen was obtained from the first instrument made, but since then slight alterations have aided towards the perfection of the instrument, so that it is now more rapid and capable of working through longer distances. As we have previously hinted, the apparatus will undoubtedly add to the reputation of the inventor. We must leave for another opportunity the consideration of the commercial and electrical value of this instrument as compared with those we already possess. Whether, however, it finds a place or not in our telegraph offices, the ingenuity shown in its construction remains the same, and should be duly acknowledged.

P. LE NEVE FOSTER.

By the sudden death of Mr. Peter Le Neve Foster, M.A., the Society of Arts has sustained a severe loss. During the past two months Mr. Foster has suffered much from gout, but it was thought that the disease had left him, as he was recently enabled to resume his duties at the society. On Thursday last, however, immediately on his return to Wandsworth, where he resided, he was seized with a sudden attack of heart disease (angina pectoris). He had been left sitting alone reading, when a member of his family, returning after a short absence, found him fallen back in his chair and dead. No anxiety had been felt in respect to his health, as may be known from the fact that he had completed his ordinary day's work at his office, and had walked up from the railway station to his own house. Mr. Foster was born on the 17th August, 1809, and was the son of M. Peter Le Neve Foster of Lenwade, Norfolk. He was educated under Dr. Valpy, at the Norwich Grammar School, whence he went up to Trinity Hall, Cambridge. After having taken his degree as thirty-eighth wrangler in the mathematical tripos of 1830, he was elected Fellow of his college. He was called to the bar at the Middle Temple in 1836, and seems to have practised as a conveyancer till he became secretary to the Society of Arts in 1853, on the resignation of Mr. Grove, who became secretary of the Crystal Palace. Mr. Foster was intimately associated with all the earlier great exhibitions. He was appointed to carry into effect the provisions of the Act for the protection of inventions in the exhibition of 1851, and was also named treasurer for payment of all executive expenses in the original commission. During his secretaryship the Society of Arts has flourished, and extended its sphere of operations and usefulness very largely, and owing in no small degree to his exertions it has quadrupled its number of members and increased its resources in a still greater proportion. Much of the work of the society was originated by Mr. Foster, and all was carried out by him. Even the regular working of such a society involves a large amount of labour and responsibility, but besides this the society has been instrumental in promoting a great many public objects, and in all of these it was necessarily upon the secretary that the burden of the work fell.

From his boyhood upwards Mr. Foster evinced very great interest in several branches of science. He was one of the first to take up and practice the art of photography, and on this subject he has written a good deal in the pages of the photographic and other periodicals. He was one of the founders of the Photographic Society, and was on its council for many years. He was president of the Quekett Microscopical Club for a year, and also served from 1863 to 1866 on the council of the British Association, the meetings of which he has attended regularly for the past twenty years. For many years he acted as secretary of the mechanical section of the association. He read several papers before the Society of Arts, notably one "On Aluminium" in 1859, and one "On Bonelli's Electric Loom" in 1860, and was, of course, a constant contributor to its "Journal," the whole series of which, from the middle of the first volume, was published under his direction. His varied occupations and his frequent contributions to the Journal of the society precluded the possibility of his paying particular attention to, or writing upon any subject in particular, but through his agency many questions of great importance have been placed before the world, and discussed to advantage, that would otherwise not have been secured. Mr. Foster was of a genial and kindly nature, and, as may be supposed, leaves behind him a very numerous body of friends. He passed a large proportion of his time in his office, and many have reason to remember generous advice and help, which was at the service of all applicants, known or unknown, who came to the office in the Adelphi. Mr. Foster married in 1838 Miss G. Chevallier, daughter of the Rev. C. Chevallier, Fellow and Tutor of Pembroke College, Cambridge. On the occasion of his completion of twenty-five years' service as secretary of the Society of Arts, a committee was formed to present Mr. Foster with a testimonial. The list for this was just about to be closed, the amount subscribed being over £1200. Under present circumstances a fresh effort will be made to increase this amount, so that a fitting memorial may be presented to Mrs. Foster. Mr. Foster has left eight sons and two daughters.

thing of the labours of Morey and Livingston, althoug... others have most probably never heard of them befor... We are not certain whether Professor Thurston has eve... seen Moreslior's book, which abounds with interesting information. The chances are that he has not, for the work is now exceedingly scarce. Morey had so much to do with the rise of steam navigation that it is a pity his name should be lost in oblivion. This is what our author says concerning him:—

"In the United States several mechanics were now at work besides Fitch. Samuel Morey and Nathan Read were among these. Nicholas Roosevelt was another. It had just been found that American mechanics were able to do the required shop work. The first experimental steam engine built in America is stated to have been made in 1773 by Christopher Colles, a lecturer befor... the American Philosophical Society at Philadelphia. The fir... steam cylinder of any considerable size is said to have been ma... by Sharpe and Curtenius, of New York City. Samuel More... was the son of one of the first settlers of Oxford, N.H. He w... naturally fond of science and mechanics, and became somethin... of an inventor. He began experimenting with the steamboat ... 1790, or earlier, building a small vessel, and fitting it with padd... wheels driven by a steam engine of his own design, and co... structed by himself. He made a trial trip one Sunday mornin... in the summer of 1790, a friend to accompany him, from Ox... up the Connecticut river, to Fairlee, Vt, a distance of sever... miles, and returned safely. He then went to New York, and spent the summer of each year until 1793 in experimenting with his boat and modifications of his engine. In 1793 he made a trip to Hartford, returning to New York the next summer. His boat was a 'stern-wheeler,' and is stated to have been capable of steaming five miles an hour. He next went to Bordentown, N.J., where he built a larger boat, which is said to have been a side-wheel boat, and to have worked satisfactorily. His funds finally gave out, and he gave up his project after having, in 1797, made a trip to Philadelphia. Fulton, Livingston, and Stevens met Morey at New York, inspected his boat and made

76

ELECTRIC VOTE RECORDERS.

TO THE EDITOR OF ENGINEERING.

SIR,—It was with considerable interest that I perused your article on electric voting in your previous issue. The subject of mechanical voting occupied a considerable share of my attention about three years ago, and resulted in the patenting of a ballot voting machine in October, 1876. This machine is suitable for any number of candidates, and is designed to meet the requirements of parliamentary, municipal, and school board elections.

A small working machine representing voting in a three-cornered constituency, formed one of the British Association exhibits in 1876. The machine was subsequently brought before the Philosophical Society of Glasgow in 1877, and as the subject of electro-mechanical voting is at present before your readers, a short description of the model machine may not be out of place.

The external and working parts of the machine consist essentially of voting handles, mechanical counters, and continuous register. At one side of the machine are four handles or bell-pulls. Over each of these handles is a candidate's name. At the opposite side of the machine are mechanical counters to indicate the number of votes which each candidate receives, also a counter to indicate the total number of votes given. Through the glass panel can be seen two rollers, upon one of which is placed a strip of paper sufficiently long to register all the votes that are intended to be given in that booth in which the machine is placed. The other roller receives the paper after it is printed and punched. On the end of the machine is a crank-handle, also a counter to indicate the number of voters. The machine is placed in a private apartment of the booth, with a crank-handle passing through the partition. Before polling begins it is the duty of those persons who are in charge of the booth to see that all the counters indicate or "are at" zero, after which the dials of the candidates' counters should be covered and locked. The *modus operandi* in voting is as follows: The first voter enters the booth and receives a ticket numbered 1, and which number should be placed opposite his name in the voter's roll. The voter then gives his ticket to the person in charge of the voting machine, who immediately turns the crank-handle one revolution, which will cause the counter on the end of the machine to indicate 1. The voter then enters the apartment and pulls out either of the candidates' handles until a bell rings, and allows it to go back to its former position. When the bell rings a vote is recorded on the candidate's counter who received the vote, also a hole is punched in the strip of paper in one of the squares opposite the voter's number and in line with the candidate's name. The voter can give two votes, not more, although he should pull the handle more than twice. The person who turns the crank-handle cannot turn it more than one revolution at a time, neither can he turn it back. By unlocking the cover of the candidates' dials, the state of the poll can be seen and made known in a few seconds. Should a scrutiny of the voting be required, the machine-made register, together with the voters' roll, will show how every elector voted.

The machine can be made to suit any election, but is specially adapted for three-cornered constituencies, as by its use three members could be returned to Parliament with the minimum number of votes, as well as under the open system of voting.

Feb 79

I am, Sir, yours respectfully,

Glasgow. ALEX. TURNBULL.

COWPER'S WRITING TELEGRAPH.—Mr. Cowper's new "Writing Telegraph" will be brought before the Society of Telegraph Engineers at their next meeting on the 26th inst.

Feb 79

Apropos of the claim made in favor of Prof. Dolbear, to have anticipated Mr. Cowper in the invention of the ingenious writing telegraph which bears his name, the London *Telegraphic Journal* of late issue declares that there is no valid ground for the claim, and that while the two inventions have the same object in view, the methods by which the object is attained are essentially different.

Aug 79

CLERAC'S ELECTRIC VOTE RECORDER.

CONSIDERING the amount of time lost in reckoning up the results when voting is carried on by ballot, or by any of the older methods, and the inaccuracy to which these are liable, it is not surprising that various automatic systems giving at once correct and rapid registration of votes should have been invented. In France, especially, much attention has been paid to this subject, and we find that as early as the year 1860, M. Salgey, inspector of telegraphs proposed to the senate of that country to apply electricity to this purpose; but the death of that gentleman prevented his ideas being practically carried out. Later, in 1870, M. Clerac, director of telegraphs, Paris, and now well-known in connexion with the Edison-Hughes controversy respecting the microphone, as the first discoverer of the principle of the variable resistance of finely divided carbon under pressure, in conjunction with M. Guichenot, civil engineer, presented to the Corps Legislatif, Paris, a complete electric system of automatic voting. Later still, in 1874, M. E. A. Jacquin, an employé of the French Telegraph Service, proposed to the National Assembly a purely mechanical arrangement, having the same object in view.

The system of MM. Clerac and Guichenot is now used for voting in the Chamber of Deputies, Paris. It possesses many notable advantages over the old methods. For example, it permits the whole assembly to see the progress of the ballot going on, and consequently, to cast up the results for themselves even before they are proclaimed; it collects the votes and totalises them instantaneously; it records them by permanent marks, and it gives to each deputy the means of assuring himself that his vote has been properly received and recorded. There is no room for false voting.

On each side of the speaker's chair are placed two large presses or cabinets divided into as many compartments as there are members in the assembly. One of these voting presses is intended to receive the *ayes* and the other the *noes*, or as they are termed in France, the *contres* and the *pours*. Each deputy possesses a compartment or box for *contre* in the negative cabinet, and one for *pour* in the positive cabinet, and he records his vote in one or the other without leaving his seat, by means of an electro-magnetic arrangement. On his desk, in front of him, are placed two press-buttons ($t\ t$, Fig. 2), which are connected to the two boxes in the cabinets at his service by wires in circuit with a voltaic battery kept in a side room of the assembly-hall. On pressing one or other button, he records his vote *pour* or *contre* in its proper box, and he is enabled to see for himself that it has been faithfully done.

This is effected as follows: Fig. 1 is a plan representing the interior of a compartment or box of the voting cabinet *s*. The apparatus there shown consists of an electro-magnet E, having an armature A which acts as a detent, holding back a small metal shutter V which is painted a showy colour, and at the same time restraining a stout arm *b* which is movable round an axis *a*. The curved tube T, which has a slight inclination downwards, contains a number of ivory balls, one for each question to be voted (twenty are generally sufficient). It has a hole in its side, at the lower extremity, which will only allow one ball to escape at a time, when it is pushed through into the chamber *l*. A small window pane *f* is fitted into the front of the box which faces the assembly. D is a shaft which runs along all the boxes in each vertical row of a cabinet, and it carries a small lever *c* in each box. Its purpose will appear presently.

Now, when the member to whom the box belongs presses the corresponding button on his desk, the battery circuit is completed, and a current flows through the electro-magnet E in the box; the armature A is consequently attracted, it thereupon releases the painted shutter *v*, which wheels round into the position v^1 shown by dotted lines, urged by a powerful spring *r*, and presents itself as an indicator in front of the glass pane *f*, thus informing the voter of the accuracy of his voting. At the same moment the arm *b*, obeying also the impulse of the spring *r*, pushes a single ball through the lateral aperture into the chamber *l* which conducts the ball into a long vertical tube into which it falls. This tube, which is so narrow as to hold only a single row of balls, one above the other, is a general collecting tube for the whole cabinet. It is of glass thickly graduated, and each gradation is exactly the height of a ball, so that members can read off the number of collective votes by the top of the column of balls as the voting goes on. When first invented, in 1869, there were only seventy deputies in the French National Assembly, and one tube was sufficient to hold all the balls; but as there are now seven hundred and fifty members, three tubes are necessary. It is worthy of mention, that instead of casting up the total by *counting* the balls, it may be done by *weighing* them.

When the votes have been taken upon any question the apparatus is re-set for another voting operation, by turning the shafts D from the outside of the cabinet. This has the effect of raising the shutter *v* into its first position under the hold of the detent A and withdrawing the push-lever *b* from the tube T. All the balls are alike, but those belonging to each deputy have his number or his name engraved on them. Each box is independent of the others.

Fig. 1.

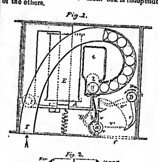

Fig. 2.

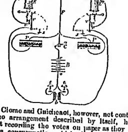


MM. Clerac and Guichenot, however, not content with the arrangement described by itself, have aimed at recording the votes on paper as they are made; a consummation which they have effected by means of electro-chemical printing. The same current which causes the indicator to appear and the balls to fall is made to print the name of each deputy and the nature of his vote on a paper register. The printing press is very simple. It consists of a printing tablet composed of a matrix of hard rubber insulator, in which are set rows of small metal blocks, each particular block having its upper face carved in relievo with the name of a particular deputy, or the number of his bench, and thus forming a block of type. Over this printing tablet a plate of zinc is made to fold, but between this plate and the face of the tablet a sheet of chemically prepared paper is inserted. Blotting or other absorbent paper, impregnated with potassium ferro-cyanide and ammonium nitrite, and moistened with water, answers very well for this purpose. Wires are led from each metal type block to the battery and press buttons or signalling keys of each deputy ($t\ t^1$, Fig. 2), and from the zinc cover, so that when the printing circuit is completed by closing the contact of the press buttons, the current flows from the type blocks through the prepared paper to the zinc cover, and thence back to the battery, decomposing the chemical solution in its passage, and printing the paper with the name on the type block, whatever it may be. As this impression is lasting a durable record is obtained of the vote. If each deputy has two blocks for his use, one of iron and the other of copper, the iron one will give a blue mark on the paper, and the copper one a brownish-red impression. In this way blue lettering may be obtained for his *pour* votes, and red for his *contre* votes, thus distinguishing their character. A single press may, by this plan, serve to operate along with the two cabinets; but MM. Clerac and Guichenot, for the sake of greater distinctness, prefer to employ two separate presses, one for the *pour* cabinet and one for the *contre* cabinet. On each of these presses there is a type block for every deputy, in connexion with this particular press button and voting-box in the cabinet; the block in the *pour* press may be of iron, and yield a blue stain, while that in the *contre* press may be of copper, and give a red stain, but with two presses this condition is not essential. Fig. 2 represents the complete vote recorder of MM. Clerac and Guichenot, combining the printing press and the ballot; $t\ t$, as we have before seen, are the press buttons installed on the deputy's desk; and, in order to guard against error as much as possible, a small galvanoscope is placed between the buttons, so that the deputy can tell whether or not the current is flowing properly in the circuit, and the printing and balloting is being effected. If by any cause the current is interrupted, the deputy will know how to correct the default by giving a notice to the scrutineer of votes. The central organ C of the figure is a commutator, placed upon the speaker's desk, for the purpose of enabling him to place the automatic voting apparatus only at the disposal of the assembly during the time of the ballot. It will readily be seen that on closing either of the press buttons $t\ t$ the circuit is completed through the electro-magnet of the deputy's ballot-box, in one or the other cabinet, according to the button pressed; the armature is attracted and liberates the shutter *v*, while at the same time a ball is allowed to fall into the collecting tube. The shutter *v*, in closing, makes contact with the stop S or S^1 of the printing press, and completes the branch circuit through the corresponding press P or P^1, thus printing the deputy's name on the prepared paper. The galvanoscope being wound with a very few turns of wire, it gives but a very small deflection at first, while the current only flows through the electro-magnet; but when, in the act of printing, the branch circuit through the press is closed, a larger deflection of the needle is obtained, and thus the latter indicates both acts of the voting, the balloting and the printing. A single large Marie-Davy element suffices for each deputy.

This arrangement permits of secret voting being carried on, by covering up the cabinets with blinds, and substituting blank blocks in the printing press for those bearing the marks of the deputies. This can easily be effected by a special construction of the apparatus. The printing press, indeed, need not be limited to voting; it may also be usefully employed as a means of calling the roll, and for other similar purposes. The multiplicity of electro-magnets and other apparatus necessary appears to give an objectionable complexity to the system, but it should be remembered that every electro-magnet is contained in its own compartment and has its own independent circuit, so that the individual apparatus of each deputy do not interfere with one another. However, the automatic ballot-boxes are not absolutely essential, for voting can be correctly carried on by the electro-chemical press itself, thus saving all the expense of the former more intricate device. The electro-automatic voting apparatus we have described is one of those ingenious contrivances which, although their usefulness and economy are apparent to all who understand the subject, are not readily adopted in practice, partly because of the limited field for their application, the force of established habits, and the unscientific training of those who are intended to use it.

In conclusion we should remark that the system of M. Jacquin, which is later than that of MM. Clerac and Guichenot, closely resembles the latter, and consists of an automatic ballot-box, actuated by electro-magnetism, but without the addition of an electro-chemical printer. The only important difference between the two systems is that instead of the chemical printer M. Jacquin provides a pointer or style also actuated by the electro-magnet, which marks the votes on strips of paper, but in a manner which renders them invisible to the assembly.

18

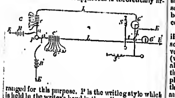
COWPER'S WRITING TELEGRAPH.

The most recent of the brilliant series of telegraphic marvels which has from time to time, and especially of late, engaged the attention of the world, is the "telegraphic pen" of Mr. E. A. Cowper, the well-known engineer of Great George-street, Westminster. This ingenious apparatus, which constitutes the first real telegraph, was publicly shown by its inventor at the meeting of the Society of Telegraph Engineers on Wednesday, February 26, before one of those overflowing audiences which only assemble there on great occasions, such as the exhibition of the telephone, the phonograph, or the microphone attracted. The telephone enables us to talk to a distance by wire; but words are fleeting things in spite of phonographs; and an instrument which permits us to *write* at a distance is a valuable addition to telegraphy.

There had been no lack of *copying* telegraphs hitherto. We have Bakewell's, Caselli's, Meyer's, and D'Arlincourt's, so recently tried at our General Post Office by Mr. Preece. All of these instruments telegraph an almost perfect *copy* of the writing or sketch submitted to them by means of synchronous mechanism. But the process is necessarily complex and slow; whereas by the new device a person may take the writing pencil in his hand, and himself transmit his message in the act of writing it, so that could his eyesight reach so far he would see the duplicate pen at the distant end of the line tracing out the facsimile characters as he formed them, just as if his arm had been lengthened out to that extent. The simple speaking telephone displaced a number of more complex tone telephones; and so it is also highly probable that Cowper's writing telegraph will in time supersede the older copying telegraphs we have mentioned.

The principle which guided Mr. Cowper to a solution of the problem which he has successfully overcome, is the well-known mathematical fact that the position of any point in a curve can be determined by its distance from two rectangular coordinates. It is upon a similar principle that a ship's course at sea is plotted upon the chart by means of latitudes and longitudes. It follows, then, that every position of the point of a pencil, stylus, or pen, as it forms a letter, can be determined by its distance from two fixed lines, say the adjacent edges of the paper. Moreover it is obvious that if these distances could be transmitted by telegraph and recombined so as to give a resultant motion to a duplicate pen, a duplicate copy of the original writing would be produced. But inasmuch as the writing stylus moves continuously over the paper, the process of transmission would require to be a continuous one, that is to say, the current traversing the telegraph line, and conveying the distances in question (or what comes to the same thing, the up and down, and direct sidelong ranges of the stylus) would require to vary continuously in accordance with the range to be transmitted.

Mr. Cowper effects this by employing two separate telegraphic circuits, each with its own wire, battery, sending and receiving apparatus. One of these circuits is made to transmit the up and down component writing of the pencil's motion, while the other simultaneously transmits its sidelong component. At the receiving station these two components are then recomposed by a pantograph arrangement of taut chords, or levers, and the resultant motion is communicated to the duplicate pen at that place. The plan adopted by Mr. Cowper to transmit each continuously varying component is to cause the resistance of the circuit to vary very closely with the component in question. The annexed diagram shows how the apparatus is theoretically arranged for this purpose.



P is the writing stylo which is held in the writer's hand in the ordinary way, while he shapes the letters one by one on paper pulled uniformly underneath by means of clockwork. To P are attached, at right angles, two arms *a a*, one for each circuit; but as it is only necessary to consider one of the circuits, say that sending up and down motions, we will confine our attention for the present to the arm *a*. One pole of the sending battery B is connected to the arm *a*, the other pole being connected to earth. Now the arm *a* is fitted with a sliding contact at its free extremity, and as the pencil P is moved in writing, *a* slides lengthwise across the edges of a series of thin metal contact plates C, insulated from each other by paraffined paper. Between each pair of these plates there is a resistance coil C, and the last of these is connected through the last plate to the line L. It will be seen that as *a* slides outwards across the plates the current from the battery has to pass through fewer coils, since *a* short-circuits a number of coils proportional to its motion. But the fewer of these coils in circuit the stronger will be the current in the line; so that the extent of the motion of the arm *a* in the direction of its length, that is to say the direct component of the motion of the pencil along the line of the arm *a*, is attended by a corresponding change in the current traversing the line. If the pencil makes a long up and down stroke there will be a strong current in the line, if a short one there will be a weak current, and so on. A precisely similar arrangement is used to transmit the sidelong motion of the pencil along the line L.

The current from the line L flows at the receiving station through a powerful galvanometer G to earth. The galvanometer has a stout needle, one tip of which is connected to a duplicate pen P', by a thread *t*, which is kept taut by a second thread stretched by a spring *s'*. The current from the line L' flows through a similar galvanometer G' to earth. The needle of G' is also connected to the pen P' by a taut thread *t'*, stretched by means of the spring *s*. Now, since the needle of each of these galvanometers deflects in proportion to the strength of the current flowing through its coil, the points of these two needles keep moving with the varying currents. But since these currents vary the motions of the sending pen, the receiving pen controlled by the united movements of the needles will trace out a close copy of the original writing. We annex a facsimile of a sentence written by Mr. Cowper's telegraph, samples of which were distributed at the meeting last Wednesday.

Telegram from our own correspondent

The receiving pen is a fine glass siphon drawing off aniline ink from a small glass holder. There are thirty-two coils C in each circuit with a corresponding number of contact plates *c*, so as to get accuracy of working. A few Daniell's cells are sufficient to operate the apparatus, and writing has been already sent successfully over a line 40 miles in length. The writing may be received either of the same size or larger or smaller than the original as the case may be. At present the writing must not be too hurried, that is, unless the characters are bold and well formed; but further improvement will of course quicken the working of the apparatus.

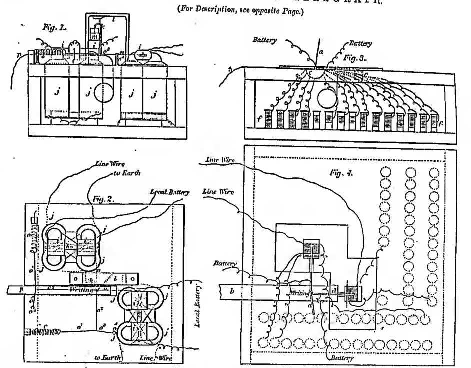
Cowper's writing telegraph is destined to supplement the telephone as a business telegraph, its great merit over the latter alone, consisting, as was before pointed out, in the fact that it gives a written record of the message, and if need be, a record written in the very handwriting of the correspondent. This property of allowing any one who can write to manipulate it, will also render it useful as a field, military, and a private and confidential telegraph. It will, of course, admit of all kinds of general orders from commanding officers or code and cypher dispatches being sent, and it will prevent cabalistic signs, unintelligible to any except those in the secret. In the same way, shorthand reports may be sent direct to newspaper offices by "our own correspondent."

The engravings, Figs. 1 to 4, on the opposite page, illustrate the actual apparatus. Fig. 4 is a plan of the sending instrument with the writing pencil *a*, the travelling paper *b*, the light connecting rods or arms *d* (which correspond to *a* in the theoretical diagram above), the series of metal contact plates over which these arms slide, the resistance coils connected to these plates, and the battery and line wires. It will be seen that each arm *d* is connected to its particular battery, and each set of contact plates to its particular line. Fig. 3 is an elevation of the sending instrument, in which *a* is the pencil as before, *c c* the contact plates over which the arms *d d* slide, *f f* the coils, and *b* the travelling slip of paper.

Fig. 2 is a plan of the receiving instrument, in which *h h* are the light pivotted needles surrounded by coils of fine insulated copper wires *i i*, and controlled in their zero position by the electro-magnets *j j j j* placed underneath, the whole forming a pair of galvanoscopes or current detectors, one for each line. It will be understood that the varying currents from the lines are allowed to flow through the coils *i i*, so as to deflect the needles, and that the deflections of the needles follow, so to speak, the variations of the currents. The electro-magnets are magnetised by a local battery; permanent magnets might, however, take their place with a gain in simplicity. Now the writing pen *k* is connected to the nearest tip of the needle *h* of each galvanoscope by threads *n n*, which are kept taut by the fibres $o, o_2\ o_3$, the springs *o* and the pins o_4. In this way the motions of the needles are recombined in the motion of the duplicate pen upon the paper *p*. Fig. 1 is an elevation of the receiving instrument, in which *i i* are the coils as before, *j j j j* the controlling electro-magnets, *k* is the writing syphon dipping with its short leg into the ink-well *m*, and *l* is the bridge from which the writing syphon is suspended by means of a thread and spring. The long leg of the syphon reaches down to the surface of the paper *p*, which is pulled along beneath it in contact with the film of ink filling the point of the tube. When the syphon is at rest its point marks a zero line along the middle of the paper; but when the receiver is working, the syphon point forms each letter of the message upon the paper as it passes.

THE COWPER WRITING TELEGRAPH.

(*For Description, see opposite Page.*)



THE PROGRESS OF THE ELECTRIC LIGHT.

In the face of the most determined opposition, and notwithstanding the extravagant and ill-founded rumours started into circulation by the gas companies, and kept alive by interested as well as by ignorant parties, the electric light continues its onward progress with extraordinary rapidity and success. It could only have been expected by business men as well as by all who, by watching the times, are able to take a calm common sense view of things, that so mad a scare as was occasioned a few weeks ago in the share market on no more solid foundation than a few unscientific and unauthenticated newspaper paragraphs, would, of necessity, be followed by a great reaction, and that when the depressing action of extravagant claims had subsided, the inherent resilience of the share-market would come into play, and a similarly opposite effect would be produced. On the other hand, but few observing commercial men can have been blind to the fact that although under the forcing atmosphere of a passing excitement, scores of so-called "new" systems for electric lighting had sprung up in the night, only to wither and disappear in the daylight of common sense and experience, the electric light on a whole was marching steadily onward, gaining rather than losing strength by opposition, and surely asserting its right to be considered for its own legitimate purposes, as the light of the immediate future.

One of the principal stumbling-blocks in the way of the public taking a reasonable view of the electric light question, and which has undoubtedly contributed more than anything else to the commercial agitation to which we have referred, is the ignorance which exists as to what is and what is not the legitimate field in which electric illumination, as it exists at present, may be advantageously employed; and newspaper writers, with a few exceptions, have much to answer for in increasing rather than dispersing that ignorance. A great deal of nonsense has been spoken and written in condemnation of the electric light because it has failed, or at all events has not accomplished hitherto, the supplanting of other illuminants in our dwelling-houses and in small rooms; and even its inapplicability to the lighting of inferior streets has been urged against it, as if that and the illumination of dwelling-houses were what its promoters claim as among its principal advantages. Nothing is easier than to conjure up a giant for the sole purpose of laying him flat, unless it be the latter operation itself, and it is interesting to notice how persistent is the inapplicability of the electric light to purposes for which, in its present stage, it is obviously inappropriate, not more on account of its cost than by reason of its great power. Similar objections might be raised, for interested motives, against lighthouse apparatus for the reason that a first-order dioptric apparatus is inapplicable to the illumination of a dining-table, or against public bells because "Big Ben" could hardly, without inconvenience, take the place of a dinner gong. Within its proper domain the electric light, in good hands, has no competitor worthy of its steel, and although we would be far from saying that electricity will *never* at any period produce the light of the future, even for the illumination of private dwellings, still that is to all intents and purposes as far off as it was fifty years ago, and unless some discovery be made which will be little short of a revolution of the whole science of electricity, gas shareholders need not have their rest disturbed on that score for a single moment. They have far more to fear from other quarters, and perhaps the philosopher's dream of "bottling up" sunlight and using it in the hours of darkness, may yet prove not so visionary after all, at all events there are upon the scientific horizon in this direction indications of the rising of a little cloud no bigger than a man's hand which may yet come to be regarded as not altogether insignificant.

Without overstepping the boundary line which encloses its special domain, the electric light has a great immediate future before it; its perfect applicability to the lighting of great halls, theatres, and other public buildings, as well as to the illumination of shops, factories, docks, squares, streets, and extensive building operations carried on at night, to say nothing of its special application to lighthouses and ships, and to naval and military operations, give to it an impregnable commercial position, and one which menaces the gas interest in some of its most valuable strongholds, and it is little but short-sighted folly for the gas companies to content themselves with issuing to their shareholders, or publishing in the public press, unscientific and absurd reports which can only have the ultimate

THE ELECTRO-PANTIGRAPH. 79

HAMILTON, OHIO, *April 5.*

To the Editor of the Journal of the Telegraph:

I NOTICE in the last number of the JOURNAL OF THE TELEGRAPH a description of Cowper's Writing Telegraph system, and editorial remarks on the efforts to claim credit. I am never a claimant for things I *intended* to do, and do not wish to be classed as such.

I, with many others, may have given thought to subjects tending toward a certain end, but when some one else presents thoughts in a material shape, he and he only is entitled to credit. We have *talked* of what we would do, what we could do, and what we wanted to do. What good does that do the world? Mr. Cowper presents the world with something *done*, not *talked* about. It should be understood by those who flood the world with evanescent thought from massive minds, that he who first presents a tangible and useful something is the proper person to receive any applause the subject may merit.

The device presented by me to the Electrical Society of the Ohio Valley is interesting and plausible, and worth study, and the idea of presenting the thing to the Society was suggested by the announcement of Mr. Cowper's *work.*

J. W. SEE.

THE WRITING TELEGRAPH. June 79

COWPER's writing telegraph has been placed on the London and South-Western Railway, and has been working most successfully from Woking to Waterloo, a distance of 26½ miles, writing off the messages in ink, one after the other, in a perfectly legible manner, whether regular line messages or messages made up in order to give the instrument more work to do. On some days more resistance coils of wire have been introduced into the two line wires, in order to represent greater distances, and thus 62½ miles and 99½ miles have been worked through in a most satisfactory manner, it only being necessary in such cases to add a few more cells of the battery, which in no case was as powerful as is very often used on the same line. The effect of the currents through the multitude of other line wires, in close proximity to the two in use for the writing telegraph, was closely observed, and the effect of induction was so exceedingly small, as only to produce occasionally a slight roughness in a straight line, when the pencil of the operator was quite stationary, but such effect was hardly ever perceptible in the writing itself, and never to affect its legibility. We understand improved instruments are now being constructed, and will shortly be at work. The fact of this instrument requiring no clerk to receive the message, translate and write it down, seems to be much appreciated, as a half-a-dozen such instruments may be telegraphing their yards of messages into one office without the least assistance from the clerk, who may from time to time cut off and send out the ready written messages; so that not only is the time of "calling"—as with ordinary instruments—saved, but the time of waiting till the clerk can attend at the other end of the line to receive the signals, which very often amounts to a much longer interval than is required for the whole message to be transmitted, especially in offices fitted with many instruments. There is also a great advantage in having an absolute record of what has been sent by the writing telegraph at the transmitting station. Another very important feature is the facility with which all that it is necessary to learn to use the instrument may be found out in five minutes. Every operation is exceedingly simple, and there are practically no fine adjustments anywhere. Variation in the power of the battery is of no importance, as its effect may be overcome by simply pushing the levers, carrying the springs against which the needles pull, a little farther in or out, as may be necessary. The pen, which is a very small glass capillary syphon tube, is, though of glass, very strong—it may fall several feet on to a bare floor without breaking—and is very easily adjusted. The writing telegraph presents facilities and advantages which, we believe, will make its adoption rapid and extensive.

21

EDISON OUTRIVALLED. April 79

TALKING BY THUNDER AND LIGHTNING.

A NEW AUTOGRAPHIC TELEGRAPHIC SYSTEM, BY MEANS OF WHICH A MAN CAN TRANSMIT HIS OWN HAND-WRITING HUNDREDS OF MILES AWAY.

At the last meeting of the Electrical Society of the Ohio Valley, held at their rooms in this city, on the evening of March 19th, Mr. James W. See presented a detailed description, illustrated by photographs, of his new autographic telegraphing system, which he terms the Electro Pantograph. Mr. S. has had his European specification in London over two years, and as the public presentation of the subject before the above-named society, of which he is a member, was the direct result of an article appearing in our columns some days ago, to the effect that a similar system was soon to be made public in London, we have felt called upon to go over the papers read before the Electrical Society, and digest it for the benefit of our readers.

By means of this system one may walk into a telegraph office, pick up a lead pencil, stick its point through a hole in the end of a pointed rod attached to the instrument, and write his message, or letter, or check, or note of hand, in any language, short-hand or long-hand, good writing or bad, and as he does so a similar pencil at a station hundreds of miles away follows every movement, and this pencil coincidently produces a perfect duplicate of the author's writing. This affair opens up fine questions as to what constitutes a legal note of hand. There can be no doubt but what such a note is actually written by the maker. No intermediate process intervenes between the maker and the distant note, and the law does not say how long or how short a pencil must be, or whether it is to be made of wood and black-lead, or of wire and batteries, and retorts and electro-magnets and mechanism.

Mr. See's system is based on the theory, fully demonstrated in his paper, that lines, no matter how complex they may be, possess but two essential elements—direction and length; and that there are but four fundamental directions; and that all possible directions are formed by a combination of two of these fundamental directions. The fundamental directions are down, left, right, and up. The effect of a combination of two directions is fully defined by the well-known philosophical laws of resultant forces, the fundamental elements of all lines being the components.

The instrument consists of four keys closing four electric circuits. These keys are opened by the rotation of toothed pinions, and the pinions are rotated by toothed racks, having articulated rods attached. The pencil socket is at the juncture of these rods. A movement of the pencil in one direction will affect a series of breaks in one circuit and not affect the other three. The number of breaks is in proportion to the length of the line. If the pencil be moved in a curve it will result in a series of breaks in two circuits, and the relative number of breaks will depend on the relation between the two component directions of the curved line. The receiving features of the instrument are similar to the portions just described, save that instead of rotating pinions breaking a circuit breaks in the circuit are caused to rotate the pinions. This is accomplished by means of four electro magnets whose armatures at each break in the circuit rotate the pinion as far as the pinion which broke the circuit rotated.

The instrument thus possesses vast executive powers. It analyzes the writing as it is produced, separates it into its component elements; transmits one of these elements over one circuit and another over another circuit at the same time; and as a receiver it receives separately the component elements of lines; properly combines them, and delivers them exactly as received. The author at the sending end places his pencil at the top of his sheet of paper; the weird pencil at the receiving station takes its position at a corresponding spot upon its sheet of paper; the author finishes a line and returns to commence a new one; the receiving pencil returns to commence its new line, and when the sender finishes and gives the final flourish to his signature, the obedient receiving pencil passively does the same, and waits for more influences from abroad. When the sender lifts his pencil from the paper and returns to cross a t or dot an i, the receiving pencil lifts; moves mysteriously through the air, crosses its t, &c., and goes on as the sender does.

This lifting of the pencil is effected by means which have not yet been described. The pencil at the receiving office, stands normally away from the paper, but is held down to the paper by an electro-magnet as long as a fifth circuit is closed. This fifth circuit is kept closed by the sender's pencil being down. If the sender lifts his pencil this circuit opens; the electro-magnet loses its force, and the receiving pencil lifts from the paper to return only when the sending pencil does.

But a single instrument is employed, it being both a sender and a receiver, and any number of them may be placed in a single line. The normal condition of the instrument is "out of action." The usual signals are employed upon any one of the circuits, and upon a station being called, a response given, the sheet placed in position, the pencils placed in unison, and the receiving lever turned; the pencil begins its magic journey.—*Cincinnati Enquirer*, March 23d.

VOL. XII. NEW YORK, JUNE 16, 1879.

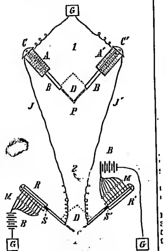
THE WRITING TELEGRAPH.

PROF. A. E. DOLBEAR, Tufts College, Mass., communicates the following description of his writing telegraph to the *New England Journal of Education:*

When a current of electricity is sent through a hollow coil of wire the latter is made a magnet, and will attract into it a short rod of iron. If the helix be held vertical, the rod of iron may be supported in the air without touching anything, through the strength of the attraction. If the iron rod be placed end to end of the coil, it will be attracted into it with a force proportional to the strength of the current of electricity in the coil. I have utilized this in making a galvanometer, the iron rod or core being supported by a spiral spring; the distance the cord is drawn into the spiral is the measure in weight of the strength of the electrical current. This same device is also employed in the receiving instrument of the writing telegraph (see 1 in the diagram).

Let A be a hollow coil of wire, and B the core of soft iron held in place by a spiral spring within the helix. At P is a marker attached by a light rod to the end of B, so that any movement made by B toward C, the bottom of the helix, would cause P to make a straight line in the same direction. Now let a current of electricity enter the helix by the wire, l, and at once B will move into the coil a certain distance; a stronger current would make it to move still further in, and a weaker one would allow the spring to push it back again; the marker then would make a straight line. At A' and B' is another fixture, precisely like the one described; they are at right angles to each other, and their common junction is at P, so that any movement made at B' will make P record the direction. When these two act conjointly, the place that P will have will depend solely upon the distance each of the cores, B and B', is drawn into its helix, and when the helices can turn upon pivots at C and C' it is plain that the point, P, may take any position inside the space indicated by the dotted lines; that is, any kind of a figure may be drawn by P inside those limits. This instrument is called the receiver.

The transmitter (see 2 in diagram) is a separate instrument, and unlike the receiver. At R is a narrow strip of wood having a groove in it, in which S may slide. On one side of the groove are a series of wire terminals of the battery, B. The end, S, of the slide is metallic, and it is in connection with the wire, l; and when it is thrust a little way into the groove it touches one of the wire terminals of the battery and permits a current of electricity to flow into the wire, l, and so through helix, A, drawing B in and causing P to make a short mark. If S is thrust into R still further, a stronger current is thrown on the line, l, and so on the farther it is down the groove. At P' is a marker corresponding to the marker in the receiver, so it will be understood that P will duplicate the motion of P'. In like manner as in the receiver, there is a second part in the transmitter, at right angles to the first, and its slide, S', is in connection with the marker, P', and with the terminals of the battery, B', so a current over the line, l', will move B' in the receiver. The other terminals of the batteries, G and G', are in the earth. It is evident that P' may be at any point within the limits of movement of R and R', and also that any new position will vary the current on one or both lines, l and l'; hence any movement of P' will be duplicated by P. For writing a strip of paper moved by clockwork under the point, P, will give a facsimile of what is written at P'. A profile or portrait, or indeed any kind of marking whatever, at P', will be duplicated by the receiver. The arrangement for varying the current from the battery, B, consists of a series of coils of wire having different resistances, as shown at M M.



PROF. DOLBEAR'S WRITING TELEGRAPH.

The main part of this invention was made by me some years ago, and it is alluded to in the book on "The Telephone and Phonograph," by George B. Prescott (p. 261). A device quite similar to this has lately been invented and described by Mr. Cowper, of England. His receiver, however, consists of two electro-magnets at right angles to each other, and the varying current acts so as to twist a light needle very much as in a common galvanometer. This transmitter is identical with mine. My instrument was made and shown to a good many persons when Cowper's was first made public here.

The Writing Telegraph.

Cowper's writing telegraph has been placed on the London and Southwestern Railway, and has been working most successfully, says the *Engineer*, from Woking to Waterloo, a distance of 26½ miles, writing off the messages in ink, one after the other, in a perfectly legible manner, whether regular line messages or messages made up in order to give the instrument more work to do. On some days more resistance coils of wire have been introduced into the two line wires, in order to represent greater distances, and thus 62½ miles and 99½ miles have been worked through in a most satisfactory manner, it only being necessary in such cases to add a few more cells of the battery, which in no case was as powerful as is very often used on the same line. The effect of the currents through the multitude of other line wires, in close proximity to the two in use for the writing telegraph, was closely observed, and the effect of induction was so exceedingly small as only to produce occasionally a slight roughness in a straight line, when the pencil of the operator was quite stationary, but such effect was hardly ever perceptible in the writing itself, and never to affect its legibility.

We understand improved instruments are now being constructed, and will shortly be at work. The fact of this instrument requiring no clerk to receive the message, translate, and write it down, seems to be much appreciated, as a half-dozen such instruments may be telegraphing their yards of messages into one office without the least assistance from the clerk, who may from time to time cut off and send out the ready written messages; so that not only is the time of "calling" (as with ordinary instruments) saved, but the time of waiting till the clerk can attend at the other end of the line to receive the signals, which very often amounts to a much longer interval than is required for the whole message to be transmitted, especially in offices fitted with many instruments.

There is also a great advantage in having an absolute record of what has been sent by the writing telegraph at the transmitting station. Another very important feature is the facility with which all that it is necessary to learn to use the instrument may be found out in five minutes. Every operation is exceedingly simple, and there are practically no fine adjustments anywhere. Variation in the power of the battery is of no importance, as its effect may be overcome by simply pushing the levers, carrying the springs against which the needles pull a little further in or out, as may be necessary. The pen, which is a very small glass capillary siphon tube, is, though of glass, very strong—it may fall several feet on to a bare floor without breaking—and is very easily adjusted.

The writing telegraph presents facilities and advantages which, we believe, will make its adoption rapid and extensive.

La Lumière Electrique

TÉLÉGRAPHE AUTOGRAPHIQUE

DE M. COWPER. July 15 1879

Lorsqu'à l'Exposition universelle de 1851, on exposa pour la première fois une dépêche écrite en écriture ordinaire par un appareil télégraphique, on ne voulut pas y croire, tant on trouvait ce résultat merveilleux, pourtant le fait était parfaitement, vrai et l'inventeur de ce système télégraphique était M. Backwel. Plus tard, M. Caselli le perfectionna assez pour le rendre applicable sur les lignes télégraphiques, et depuis une vingtaine d'années les appareils de ce genre qui ont été imaginés successivement ont été si nombreux, que, dans la description que j'ai dû en faire dans mon exposé des Applications de l'électricité, j'ai dû les répartir en cinq catégories, comprenant :

1° Les télégraphes autographiques électro-chimiques;
2° Les typo-télégraphes électro-chimiques;
3° Les typo-télégraphes à maquette;
4° Les télégraphes autographiques électro-magnétiques;
5° Les télégraphes pantographiques.

C'est à ce dernier genre d'appareils qu'appartient le télégraphe de M. Cowper dont on a beaucoup parlé dans ces derniers temps et dont nous allons donner une description complète.

Si l'on considère que tout mouvement peut être produit par la combinaison de deux mouvements rectangulaires, on arrive à conclure immédiatement que si, par un dispositif électrique quelconque, on peut gouverner régulièrement dans deux sens rectangulaires la marche d'un crayon ou d'un style quelconque, on pourra faire parcourir à ce crayon un chemin sinueux qui pourra être contourné en forme de lettres. Il s'agit donc d'obtenir électriquement ce double mouvement pour résoudre mécaniquement le problème des télégraphes pantographiques. Or, c'est ce problème qu'a résolu pour la première fois M. Lacoine, aujourd'hui directeur des télégraphes à Constantinople. Depuis lui, plusieurs inventeurs se sont également efforcés de résoudre le même problème, entre autres MM. Garceau, Leuduger-Fortmorel, Bienaymé et Hasler, mais les résultats obtenus n'ont jamais été assez satisfaisants pour que l'on songeât à tirer parti de ce système pour les transmissions télégraphiques, et c'est M. Cowper qui a pu reproduire assez nettement l'écriture par ce moyen pour fixer l'attention, et montrer que ce problème était parfaitement soluble. Toutefois, les dispositions délicates et compliquées de ce système ne semblent pas faire présager qu'il soit susceptible de devenir pratique sur nos longues lignes, mais dans tous les cas c'est une invention extrêmement curieuse qui mérite bien l'attention et l'intérêt qui l'ont accueillie. Voici maintenant la description que nous envoie de ce système M. Hospitalier.

TH. DU M.

L'ingénieux appareil imaginé par un ingénieur anglais, M. Cowper, reproduit à distance, à l'aide de l'électricité, tous les mouvements d'une plume ou d'un crayon placé au poste expéditeur *au moment même* où ces mouvements se produisent. Le mouvement pantographique du poste expéditeur et du poste récepteur sont obtenus par une application du procédé géométrique qui détermine la position d'un point sur un plan par la valeur de ses deux coordonnées.

Le déplacement du point produit des variations dans la longueur de chaque coordonnée, et ces variations sont transmises par deux fils de ligne, un pour les abcisses, l'autre pour les ordonnées, en faisant varier l'intensité du courant sur chacune de ces lignes proportionnellement à la valeur de chaque coordonnée.

Les gravures qui accompagnent cet article et que nous empruntons au *Télégraphic journal* représentent : (fig. 1) le diagramme théorique du transmetteur et (fig. 2) le plan du récepteur.

Transmetteur. Deux leviers a et a' (fig. 1) à angle droit présentent à leur point de rencontre P un trou dans lequel on introduit un crayon ordinaire qu'on manœuvre à la main pour écrire le message et qui produit ainsi le déplacement des leviers. Considérons par exemple le levier *a*. Le déplacement dans le sens horizontal du crayon placé en P a pour effet de faire glisser *a* sur une sorte de peigne R composé de 32 lames de laiton séparées par des feuilles de papier enduites de paraffine, chaque lame étant reliée à la suivante par une bobine de résistance convenablement équilibrée. Le courant arrivant de la pile B traverse le levier *a*, un certain nombre de bobines (représentée chacune sur le diagramme par une simple boucle) et va par le fil de ligne au poste récepteur. Un déplacement à droite ou à gauche du point P a donc pour effet d'introduire dans le circuit ou d'en retirer un nombre de bobines de résistance en fonction de ce déplacement. Il en résulte un affaiblissement ou un accroissement d'intensité proportionnel aux déplacements de P. Dans l'appareil que nous avons vu et fait fonctionner à Londres, la ligne étant représentée par 400 ohms de résistance, soit 40 kilomètres environ, la résistance des bobines est graduée de telle sorte que la première, à droite, ayant seulement 30 ohms de résistance, la dernière à gauche en a 600.

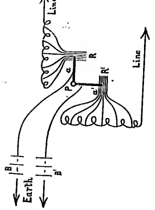

Fig. 1.

Le point P étant dans sa position extrême de gauche, les 31 bobines reliées aux 31 lames de laiton introduisent une résistance additionnelle de 10,000 ohms.

Ce que nous venons de dire s'applique aux déplacements dans le sens vertical transmis par un second fil de ligne et un second jeu de bobines de résistance correspondant au peigne R' et à une seconde pile B'.

Les leviers a et a' ne devant jamais quitter leurs peignes respectifs, les déplacements du point P sont limités par un petit cadre carré de 20 millimètres de côté environ et une bande de papier entraînée par un mouvement d'horlogerie se déroule régulièrement de droite à gauche sous ce cadre. La main restant immobile, le crayon ne peut se déplacer que de 2 centimètres en tous sens, et le papier se déroulant régulièrement sous votre main, ces conditions insolites de calligraphie constituent une petite difficulté vaincue après deux minutes d'exercice. Il suffit de remarquer que les mouvements de gauche à droite opposés au mouvement du papier doivent être très-petits, tandis que ceux de droite à gauche doivent être assez rapides, car on doit alors courir après le papier qui s'échappe sous la main.

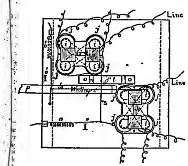

Fig. 2.

Récepteur. Le récepteur (fig. 2) se compose, pour chaque ligne, d'une paire d'électro-aimants verticaux i i, j j, dans lesquels circule le courant venant du transmetteur. Une aiguille de fer-blanc très-légère pivote autour de *h* entre les pôles de ces électro-aimants et est polarisée par le courant d'une pile locale circulant dans deux bobines horizontales qui entourent l'aiguille tout en lui permettant de se mouvoir horizontalement.

L'extrémité de chaque aiguille est reliée à un fil o2, n'2 sur lequel un faible ressort o, o' exerce une traction convenablement réglée. Au point d'intersection des fils o2 et n'2 reliés à chaque aiguille est fixé un syphon capillaire dont à une des extrémités vient s'appuyer une bande de papier p et tracer un trait continu sur cette bande qui se déroule régulièrement de droite à gauche par un mouvement d'horlogerie. L'autre extrémité du syphon *l* plonge dans un réservoir d'encre d'aniline qui sert à l'alimenter.

Les électro-aimants dont la puissance est proportionnelle à l'intensité du courant circulant dans la ligne qui correspond à chacun d'eux, produisent sur l'aiguille polarisée des déviations proportionnelles à ces intensités. La pointe du syphon écrivant suit tous les déplacements des aiguilles qui lui sont communiqués par les fils o2 et n'2 et reproduit sur la bande p tous les caractère tracés par le crayon du poste expéditeur.

Il n'y a donc pas besoin d'établir de synchronisme entre les appareils et il suffit que les mouvements d'horlogerie qui entraînent les bandes marchent régulièrement pour obtenir la reproduction de l'écriture au poste récepteur. Un déroulement trop rapide ou trop lent de la bande se traduit seulement par une *anamorphose* de l'écriture comme ci-dessous.

Si la bande se déroule trop vite, on obtient LONDRES.

Si la bande se déroule trop lentement, on obtient **LONDRES.**

Il va sans dire que le trait reproduit à la station est *continu*, aucune disposition spéciale ne relevant le syphon écrivant pour séparer les mots qui sont seulement distingués par les intervalles qu'on ménage entre eux.

La figure 3 représente un fac-simile d'une dépêche ainsi écrite et de la même dépêche transmise; comme on le voit, l'écriture à la transmission est beaucoup plus grande que celle obtenue à la réception, et cela doit être, pour que les variations de résistance du circuit soient réellement appréciables. En raison de cette différence de grandeur, nous n'avons reproduit dans le fac-simile que le premier mot de la phrase qu'on lit sur la dépêche reproduite, c'est le mot *écrit*. On peut voir, du reste, que la reproduction de l'écriture est parfaitement lisible.

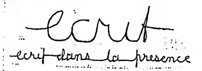

Fig. 3.

Applications de l'appareil. Le principe de cet appareil se prête à plusieurs applications intéressantes.

Dans les affaires, il pourra servir à transmettre des ordres écrits en supprimant toutes chances d'erreurs; les ordres secrets, les écritures cryptographiques et étrangères pourront ainsi s'envoyer instantanément par le même appareil.

Mais on ne pourra multiplier les applications de ce système, comme celles du téléphone dont il est en quelque sorte l'analogue pour la transmission de l'écriture, qu'après des modifications légales dont nous n'avons à apprécier ici ni l'importance ni l'opportunité.

Signalons enfin, à titre de curiosité, une modification possible de l'appareil, qui montre quelle puissance l'électri-

2 21

cité oiet en nos mains pour effectuer les choses les plus invraisemblables en apparence.

Ajoutons un troisième fil à l'appareil, un troisième peigne avec une troisième série de bobines de résistance, et obligeons la pointe du transmetteur à se promener régulièrement à la surface d'un médaillon, cette pointe se soulevant proportionnellement aux reliefs. Nous faisons ainsi de la géométrie à trois dimensions. En remplaçant le syphon du récepteur par une pointe très-fine, elle suivra tous les mouvements de la pointe du récepteur et nous reproduirons, *à une distance de plusieurs kilomètres*, un médaillon, un camée, ou toute autr objet analogue.

M. Cowper, par la solution élégante du problème de l'écriture à distance, nous montre, une fois de plus, quelle mine féconde l'électricité offre à ceux qui, pour l'exploiter, peuvent unir la science à l'imagination.

E. Hospitalier.

Le bruit qui s'est fait autour du télégraphe de M. Cowper a éveillé en Amérique certaines prétentions que nous voyons formulées dans le *Scientific American* du 14 juin 1879, à l'occasion d'un télégraphe du même genre imaginé par M. Dolbear et qui, suivant lui, aurait été décrit dans l'ouvrage de M. Prescott sur le téléphone et le phonographe.

Malheureusement pour M. Dolbear, il arrive, en admettant même l'exactitude de ses prétentions, le sixième sur la liste des inventeurs de ces sortes de télégraphes. M. Prescott aurait pu s'en apercevoir, puisqu'il a entre les mains tous les traités télégraphiques du monde entier et que j'ai décrit moi-même les cinq systèmes qui ont précédé ceux de M. Dolbear et de M. Cowper, dans les deux éditions de mon exposé des Applications de l'électricité; mais on n'aime pas, en Amérique, rappeler les inventions et les travaux étrangers. Dans tous les cas, voici en quoi consiste le système de M. Dolbear:

Dans ce système, les deux mouvements rectangulaires du style écrivant sont obtenus sous l'influence d'attractions de courants parallèles, c'est-à-dire sous l'influence de tiges de fer s'enfonçant dans des bobines électro-magnétiques proportionnellement à l'intensité des courants transmis. Naturellement ces tiges de fer sont disposées entre elles à angle droit, et la bande de papier se déroule au-dessous du style écrivant comme dans les télégraphes Morse ordinaires. Dans le transmetteur, les deux glissières à angle droit qui correspondent au style traceur sont terminées par un contact qui passe sous une série de ressorts mis en communication avec le même pôle d'une batterie, et dans le circuit desquels sont interposées une série de résistances, graduées de manière à fournir, d'une extrémité à l'autre, une variation de courants régulièrement croissants ou décroissants. Comme dans tous les systèmes de ce genre, il y a deux batteries et deux fils à la ligne, afin de pouvoir obtenir les deux mouvements rectangulaires nécessaires à la reproduction d'une figure. Or, suivant M. Dolbear, les mouvements produits par les noyaux magnétiques de l'appareil de réception se trouveraient être proportionnels à ceux exécutés par les glissières du style du transmetteur qui mettraient en jeu des courants d'intensité différente suivant leur position. Par conséquent, on pourrait obtenir la reproduction réduite (dans tel rapport que l'on voudrait) des mouvements produits par le style traceur de l'appareil de transmission.

Nous ignorons si ce système a été exécuté, mais nous croyons que cette proportionnalité des mouvements des noyaux magnétiques glissants dans des solénoïdes à l'intensité des courants transmis est au moins douteuse, car il y a dans ces sortes d'attractions un maximum qui se produit quand le milieu du noyau magnétique correspond au milieu de la bobine. Du reste, tous ces télégraphes sont, comme il a été dit en commençant, plutôt une curiosité que des appareils utiles.

Th. du M.

The Writing Telegraph.

Mining & Ex-Press Aug 11 1877

Cowper's writing telegraph has been placed on the London and Southwestern railway, and it works most successfully, says the *Engineer*, from Woking to Waterloo, a distance of 26½ miles, writing off the messages in ink, one after the other, in a perfect legible manner, whether regular line messages or messages made up in order to give the instrument more work to do. On some days more resistance coils of wire have been introduced into the two line wires, in order to represent greater distances, and thus 62½ miles and 99½ miles have been worked through in a most satisfactory manner, it only being necessary in such cases to add a few more cells of the battery, which in no case was as powerful as is very often used on the same line. The effect of the currents through the multitude of other line wires, in close proximity to the two in use for the writing telegraph, was closely observed, and the effect of induction was so exceedingly small as only to produce occasionally a slight roughness in a straight line, when the pencil of the operator was quite stationary, but such effect was hardly ever perceptible in the writing itself, and never to affect its legibility.

The fact of this instrument requiring no clerk to receive the message, translate and write it down, seems to be much appreciated, as a half-dozen such instruments may be telegraphing their yards of messages into one office without the least assistance from the clerk, who may, from time to time, cut off and send out the ready written messages; so that not only is the time of "calling" (as with ordinary instruments) saved, but the time of waiting till the clerk can attend at the other end of the line to receive the signals, which very often amounts to a much longer interval than is required for the whole message to be transmitted, especially in offices fitted with many instruments.

There is also a great advantage in having an absolute record of what has been sent by the writing telegraph at the transmitting station.

Another very important feature is the facility with which all that it is necessary to learn to use the instrument may be found out in five minutes. Every operation is exceedingly simple, and there are practically no line adjustments anywhere. Variation in the power of the battery is of no importance, as its effect may be overcome by simply pushing the levers, carrying the springs against which the needles pull a little farther in or out, as may be necessary. The pen, which is a very small glass capillary siphon tube, is, though of glass, very strong—it may fall several feet on to a bare floor without breaking—and is very easily adjusted.

Electrician Aug 30 1879

BRITISH ASSOCIATION.

THE WRITING TELEGRAPH.

On Monday, before the Mechanical Section, Mr. E. A. Cowper described details of the construction of his writing telegraph and the mode in which a pen at a distant station was made to write, freely, as the operator at the sending station wrote with a pencil at the sending instrument. He explained the necessity that existed for causing the two currents of electricity that conveyed the power to the distant station to increase steadily and gradually, without any sudden large increase or decrease of resistance being opposed to such currents; the construction of the necessary resistances being practically that of one very long thin German silver wire, having 32 metal plates soldered to it at the proper intervals, such plates being all brought very close together with simply a thin sheet of paper with paraffin between them, so that a contact rod in connection with a battery with a small knob or projection on it could slide over the tops of the plates and make contact with each one in succession. Then two such contact rods joined to the pencil of the operator and placed at right angles to one another worked over the tops of the two separate sets of contact plates, each set affecting one line wire, so as to give latitude and longitude of the pencil of the operator at all times. The quick action or perfect response of the needles at the receiving instrument, which directly controlled the writing pen, was obtained by using exceedingly thin soft iron plates, both for the needles and for the magnets which affect the needles, so as on the one hand to have the least possible amount of momentum and *vis inertia* in the needles, and the least possible residuary magnetism in the magnets. The needles were slightly curved in their section to stiffen them, their thickness being only 1-110th inch, and were mounted on polished hard steel bearings, and were thus exceedingly free and lively, as a very small amount of friction or weight in this part of the instrument would be fatal to good writing. The power of the needles was ensured by fixed flat coils that surrounded them, brought into action by a local battery, whilst the two line wires were coiled around the fixed magnets that affected the needles and attracted them more or less as the strength of the currents varied. Then the needles being at right angles to each other, pulled the pen in the two directions, vertically and horizontally, and also pulled against two light springs, so that the pen took exactly the varying positions due to the varying strength of the currents, which again depended upon the position of the pencil of the operator. The paper on which the operator wrote and the paper on which the pen wrote at the opposite end of the line both moved along by clockwork, so as to write a long continuous message or telegram.

Mr. Cowper exhibited his machine, which was carefully examined, and showed how really ingenious the inventor had been. In answer to questions, he said that the instrument had worked perfectly at a distance of 99½ miles. At present the operator could send messages at the rate of twenty words per minute, but he hoped that would be increased.

27

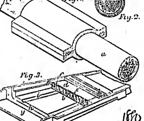
Cowper's Writing Telegraph.

Eng Mechanic Sep 5 1879

Mr. E. A. Cowper read a paper on his writing telegraph, and explained the necessity that existed for causing the two currents of electricity that conveyed the power to the distant station to increase steadily and gradually, without any sudden large increase or decrease of resistance being opposed to such currents; the construction of the necessary resistances being practically that of one very long thin German silver wire, having thirty-two metal plates soldered to it at the proper intervals, such plates being all brought very close together with simply a thin sheet of paper with paraffin between them so that a contact rod in connection with a battery, with a small knob or projection on it, could slide over the tops of the plates and make contact with each one in succession. Then two such contact rods joined to the pencil of the operator, and placed at right angles to one another worked over the tops of the two separate sets of contact plates, each set affecting one line wire so as to give latitude and longitude of the pencil of the operator at all times. The quick action of the perfect response of the needles at the receiving instrument, which directly controlled the writing pen, was obtained by using exceedingly thin soft iron plates both for the needles and for the magnets which affect the needles, so as on the one hand to have the least possible amount of momentum and *vis inertia* in the needles and the least possible residuary magnetism in the magnets. The needles were slightly curved in their section to stiffen them, their thickness being only 1-110 inch, and were mounted on polished hard steel bearings, and were then exceedingly fresh and lively, as a very small amount of friction or weight in this part of the instrument would be fatal to good writing. The paper on which the operator wrote and the paper on which the pen wrote at the opposite end of the line both moved along by clock-work, so as to write a long continuous message or telegram.

1184. Apparatus for Insulating, Containing, and Protecting Surface and Underground Telegraph Wires: J. T. King, Liverpool. (*C. Linfeld, Pittsburgh, U.S.A.*) [6d. 8 *Figs.*]—The object of the invention is to protect surface and underground telegraph wires from growth of fungus, admission of moisture, and want of durability, and to render them accessible for repairs. Fig. 1 is a perspective view of a telegraph cable and container. The cable *a* consists of cotton covered wires held together by a strip of cotton wrapped spirally round them, the interstices are filled with melted paraffine or tar. The cloth wrapper is coated with an elastic impervious material, and, if desired, another strip of cloth is wound round in an opposite direction, and also coated with material. Fig. 2 shows a section of the cable. Fig. 3 shows a container with an iron box or bed, protected from rust by tinning or other treatment. The interior is

29 R



Engineering Oct-29 1880

fluted at *b* to form receptacles for the wires, and the whole interior surfaces of them are coated with porcelain enamel, as at *c*, to prevent the passage of moisture to the interior. A cover *d* fits within the flanges *e*, and rests upon the shoulders *f*. The sections of the container are united by a coupling box *g*, which has a transverse groove *h* and longitudinal grooves *i*. The form of the coupling box is adapted to the shape of the bed, and is attached by screws. When the wires are placed in the grooves, the cover *d* is cemented down, the cement being filled into the groove *k* and between flanges *e*. Cement is also poured into the coupling box, and fills up the grooves and recesses. (March 19, 1880).

COWPER'S WRITING TELEGRAPH.

[16183.]—I was surprised and disappointed to find in your issue for March 7 an account of an invention by Mr. Cowper, by which a telegraphic message can be automatically recorded in writing similar to that written by the sender. To accomplish this had been my chief object for the previous five months, and I had pretty nearly arrived at what I thought to be a solution of the problem, when the above information reached me, as I have said, through the medium of your valuable journal. I was struck with the similarity that exists between Mr. Cowper's invention and the latest arrangement which I had arrived at to effect the required object. The principle which I made use of was the same as that employed by Mr. Cowper, and therefore I need not mention it; but far stronger is the fact that the last transmitter I devised is so like the one described in the MECHANIC of the above date, that I don't know where to point to a difference. I had thought of many different modes of varying the resistance to produce required results; one consisted in attaching to the pencil two thin wires at right angles; these pass over pulleys and terminate in small metal balls, each of which passes into a tube with a metallic bottom, and partially filled with water; the bottoms of the tubes are connected by separate wires to the receiver, and the pencil to one pole of the battery. I have so arranged matters that when the pencil is moved *directly* away from one tube, and in a direction parallel to either wire then at right angles, the height of the ball in the other tube will not be affected.

As regards the receiver, I should like to know what would be the objections to one of the following type, which is the only difference between Mr. Cowper's invention and my idea, and which is so simple that I trust a figure is unnecessary. A long thin rod has a universal joint near one end; this joint, which works with next to no friction, I designed for the purpose, though it was probably known before. Two light armatures, attached by light rigid rods to the short end of the jointed one, are placed at right angles; an electro-magnet is placed near each armature. Two springs at right angles are also attached to the rod, so as to partially counteract the force of the magnets. One end of the wire of each magnet is connected with one line wire, the other two with the earth.

In Mr. Cowper's arrangement, the needles are deflected through distances which may be taken as proportional to the amounts of current received, owing to their small deflection; but in mine, in order to produce deflections proportional to the current, the springs must be of a certain tension, since the force of a magnet varies inversely as the square of the distance from it. Perhaps iron weights, moving in coils, and attached by strings to the short end of the rod, would give better results.

The siphon arrangement, for recording the movements of the rod, would, of course, be attached to the end of the long part of the rod.

I should like to point out, in conclusion, that I don't for a moment presume to have devised a better plan than Mr. Cowper for embodying an idea which occurred to both that gentleman and to me quite independently; but rather I give it for what it is worth, with the hope that someone may think it worth the trouble of trying.

In the mean time, I shall be glad to hear the opinions of any of your many able correspondents, for, while it seems to me quite as effective a plan, it obviously has the advantage of greater simplicity.

W. B. B.

Dunedin, New Zealand, June 30.

P.S.—Is not the necessity of having two line-wires a great drawback to the new invention?

George Bower, St. Neots.

13. Cowper's Writing Telegraph.

The person sending a message by this instrument, writes with an ordinary pencil, which is jointed to two light connecting rods at right angles to each other, which transmit currents of variable strength, one for the up and down strokes, and the other for the right and left movements. These currents affect two magnets, which actuate two needles, to which a pen is connected, in the receiving instrument (which may be many miles distant from the sending instrument), and cause the pen to follow the motions of the pencil of the sending instrument, and so reproduce in ink the written message.

E. A. Cowper, C.E.

Messages will be sent from one part of the hall to another, through a coil of wire representing about 36 miles of ordinary telegraph line.

parent raison d'être in phenomena.

Boston Journal of Chemistry May 1879

HANDWRITING SENT BY TELEGRAPH.

THE Hibernian who expected to send his letter along the telegraphic wire was perhaps only a little ahead of the times. "Autographic telegraphy," or the transmission of messages in the actual handwriting of the sender, is a subject which for some thirty years has been the study of inventors. As long ago as 1850, Mr. F. C. Bakewell, in England, devised an instrument for this purpose, which was probably the first practically successful one. The message was written with a gummy ink or varnish on metallic paper or tin-foil, and this writing was by the aid of mechanism used to actuate electric currents in such a way as to produce a record at the distant station by the chemical decomposition of a solution with which the receiving paper was damped. Both the written messages and the paper were fixed around cylinders of similar form and dimensions, one being placed in the transmitting and the other in the recording instrument, and the cylinders were caused to revolve with corresponding velocities. Each time the gummy, and consequently raised, lines of the writing were crossed by a pointer, under which the metallic paper was traversed in the transmitter, a mark corresponding in position was made on the prepared paper at the receiving end. It therefore followed that the sum of all

the marks reproduced the writing itself. Mr. Bakewell successfully reproduced the writing in white on a blue ground, but the process failed to become one of public utility owing to the extreme slowness with which the apparatus worked, and the difficulty that was experienced in maintaining uniform and synchronous motion in the instruments. In 1856, the Abbé Casolli, in Italy, endeavored to solve the problem of autographic telegraphy in a similar manner. His apparatus, of which an illustrated description is given in Ganot's "Physics," was exhibited in England, and it was used practically between Paris and Marseilles, and Paris and Lyons. Plans, drawings, and autographic sketches were faithfully reproduced at distant places, but it was found that the apparatus had not only the defects of Bakewell's, but it was very costly and complicated. Two other subsequent workers in this direction were M. Meyer and M. Lenoir, who, quite unknown to each other, tried to accomplish the same results with ordinary ink.

The latest experiment in autographic telegraphy is that of M. d'Arlincourt, of Paris, which has lately been submitted to the English post-office authorities for trial. The London *Times* gives the following account of the instrument (which is on the same general plan as Bakewell's) and its workings:—

The distinguishing feature in M. d'Arlincourt's apparatus is the introduction of an extremely ingenious synchronous movement, by means of which the speed of travel of the cylinders is rendered uniform, both in the transmitting and the recording machine. The message to be sent, which may be either in the ordinary hand or short-hand, is written with a thick, gummy ink upon a strip of metallic-faced paper, about twelve inches long and two and one half inches deep, which is wrapped around the cylinder of the transmitting instrument. A strip of white paper, chemically prepared and of similar dimensions, is placed on the cylinder of the recording apparatus, and the instruments are placed in electrical connection and started. The raised writing, actuating the electric current, causes a reproduction of the original message in *fac-simile* on the paper in the recording instrument, which may be hundreds of miles away from the other. Upon the occasion of our visit the two instruments, although in the same room, were practically placed two hundred miles apart. The writing can be reproduced in either blue, brown, red, or black, according to the chemical preparation of the paper, but always on a white ground, and a number of copies can be taken from one original. In the same way, sketches, plans, or drawings may be faithfully transmitted; some sketches were, in fact, accurately reproduced on the occasion of our visit. Although the apparatus is perfect in its action, it still has one drawback, which was common to its predecessors,—that of slowness of reproduction. The time occupied in revolving the cylinder a sufficient number of times to allow the pointer to traverse the whole surface of the paper is seven minutes, and this rate of speed is far below that required and attained in practice for commercial purposes. The post-office authorities, to whom we are indebted for our inspection, do not, therefore, see their way to utilize M. d'Arlincourt's ingenious invention at present. It is, however, being worked in France in fortresses, and for similar military purposes, for use in which and in some special cases it is exceedingly well adapted.

J. C. JACOBSON, a wealthy brewer of Copenhagen, has set aside a million Danish crowns for the support of a laboratory for scientific results.

Menlo Park Scrapbook, Cat. 1044

No. 30. "Telegraph - Duplex, Quadruplex, Multiplex"

This scrapbook covers the years 1873-1889, but most of the clippings are for the mid-1870s. The material relates primarily to multiplex telegraphy. Several of the clippings for 1888 deal with Elisha Gray's telautograph and his claim to have invented the telephone. There are 138 numbered pages.

Blank pages not filmed: 2-3, 6-9, 98-138.

LE QUADRUPLEX DE M. EDISON

Les systèmes de transmissions simultanées et multiples combinés dès l'année 1855 peuvent être répartis en quatre grandes catégories :

1° Les systèmes dans lesquels les correspondances peuvent être échangées simultanément en sens contraire des deux bouts de la ligne par l'effet de combinaisons particulières de circuits ;

2° Les systèmes dans lesquels des transmissions multiples peuvent s'effectuer simultanément dans le même sens à chaque station ;

3° Les systèmes dans lesquels on utilise les instants où plusieurs appareils transmetteurs introduits dans le même circuit à une station sont inactifs ;

4° Les systèmes où les dépêches, étant transmises simultanément par des appareils électro-harmoniques, permettent le triage des dépêches par le synchronisme des vibrations des appareils récepteurs.

A la première catégorie appartiennent les duplex aujourd'hui très-nombreux, combinés pour la première fois par M. Gintl et dont il a été déjà question dans un des précédents numéros du journal l'*Electricité*.

A la seconde appartiennent certains systèmes combinés, dans l'origine, par MM. Stark et Duncker et perfectionnés ensuite par MM. Bosscha, Maron, Wartmann, etc.

A la troisième se rattachent les systèmes de MM. Meyer, Baudot, Schaeffler, combinés dans l'origine par M. Rouvier.

Enfin, à la quatrième se rapportent les télégraphes harmoniques de MM. Paul Lacour, Elisha Gray, Graham Bell et C. Varley.

La combinaison des deux premiers systèmes devait conduire fatalement au quadruplex et même en adaptant les combinaisons du duplex aux deux dernières catégories d'appareils, on pouvait doubler le nombre des dépêches envoyées. C'est ainsi que le télégraphe harmonique d'Elisha Gray, qui n'était dans l'origine qu'un quadruplex à transmission dans le même sens, est devenu un octuplex. Toutefois, on s'en est tenu généralement jusqu'ici dans la pratique, aux duplex, aux quadruplex et aux systèmes multiples de Meyer, et, parmi les systèmes employés, ceux de MM. Stearns et Edison sont les plus importants. On peut même dire que c'est grâce au système de Stearns que le duplex a été rendu susceptible d'être appliqué sur les lignes, et c'est ce qui explique pourquoi cette invention, qui remonte à 1855, n'a été appliquée qu'en 1872.

Le secret de la réussite de M. Stearns gît, comme on le sait, entièrement dans l'introduction qu'il a faite d'un condensateur dans le circuit, afin de compenser les effets des décharges dues aux réactions statiques effectuées sur les lignes.

Il paraît que c'est seulement en juin 1873 que M. Olivier Heaviside fit remarquer le premier qu'en combinant au duplex de Stearns le système à transmission dans le même sens de MM. Stark et Bosscha, on pourrait doubler le nombre des transmissions effectuées par le duplex. En 1874, M. Edison chercha à réaliser cette idée sur les lignes de la Western-Union-Company de New-York et combina le système dont nous allons parler et qui a été l'une des plus intéressantes conceptions de l'inventeur américain.

Dans ce système, les transmissions simultanées dans le même sens sont basées sur la combinaison des systèmes de transmission à courant double et à circuit ouvert. On sait que, dans le premier système, la batterie reste en communication permanente avec la ligne à la station de transmission, ses pôles étant renversés au commencement et à la fin de chaque signal, sans que jamais le circuit soit interrompu. Alors, le relais de la station de réception est polarisé et disposé de manière à n'être impressionné que par le sens du courant. Il en résulte, par conséquent, que les modifications dans la force du courant transmis restent sans action sur lui.

Dans le système à circuit ouvert, au contraire, le récepteur fonctionne sous l'influence de courants interrompus ou simplement affaiblis, et en conséquence son armature est en fer doux et soumise à une action antagoniste. Or, on conçoit que dans de pareilles conditions, deux appareils disposés, suivant ces deux principes, aux deux stations en correspondance pourront, étant convenablement réglés fonctionner isolément avec des transmissions simultanées, puisque l'un ne peut agir que sous l'influence d'une action à laquelle l'autre est insensible. Pour faire de ce système un quadruplex, il ne s'agissait que de lui appliquer la disposition du duplex. Toutefois, le choix de cette disposition n'a pas été aussi simple qu'on l'aurait pensé, et après plusieurs essais faits entre New-York et Boston, sur une longueur de ligne de deux cent quarante milles, on reconnut que la disposition en duplex avec le pont de Wheatstone était préférable à la disposition en système différentiel, surtout quand la ligne était très-longue.

La disposition du quadruplex de M. Edison est indiquée dans la figure ci-contre. T^1 est un transmetteur de courant à inversions, mis en action par un électro-aimant, une batterie locale E^1 et une clef K^1. Sa fonction consiste à renverser le sens du courant de ligne à travers la plaque de terre et la ligne, chaque fois que la clef K^1 est abaissée. Les ressorts S^1 S^2 déterminent cet effet sans que la ligne soit pour cela interrompue.

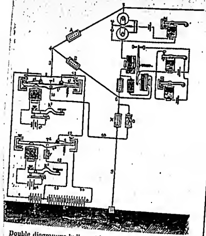
De cette manière, les mouvements du second transmetteur T^2 effectués sous l'influence d'une petite pile locale e^2 et la seconde clef K^2, peuvent transmettre à travers la ligne les courants résultant d'une seconde pile de ligne E^2 qui s'additionnent quand la clef K^2 est abaissée à ceux de la pile E^1 ayant deux ou trois fois moins d'éléments. Toutefois, malgré cette action, la polarité de la ligne se maintient dans les conditions où l'a placée la première clef K^1.

A l'autre extrémité de la ligne se trouvent les deux appareils de réception R^1 R^2, l'un R^1 qui est un relais à armature polarisée, et qui n'est, par conséquent, impressionnable qu'aux courants renversés, l'autre R^2 qui est un relais à armature de fer doux, réglé de manière à n'agir que sous l'influence des courants renforcés, et par conséquent sous l'action de la clef K^2.

Le premier de ces relais réagit par l'intermédiaire d'une pile locale L^1, sur un résonnateur S^1 qui fournit les indications en rapport avec les transmissions effectuées par le transmetteur T^1. L'autre relais actionne un autre résonnateur S^2, mais dans des conditions un peu plus compliquées en raison des mouvements produits par l'armature du relais R^2 au moment des inversions des polarités de la ligne.

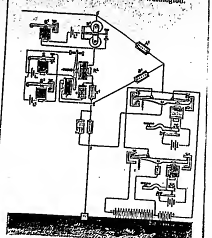
Pour éviter ces effets, il a fallu que l'armature du relais R^2 ne produise son contact de fermeture que sur son butoir d'arrêt, et c'est alors une seconde pile locale L^2 qui fait marcher le résonnateur S^2.

Poste de Boston
Station du quadruplex Edison à New-York.



Double diagramme indiquant la marche des courants pour le quadruplex Edison.

Poste de New-York
Station du quadruplex Edison à Washington.



Double diagramme indiquant la marche des courants pour le quadruplex Edison.

Avec cette disposition, il arrive que quand le relais R^2 a son armature attirée, le circuit du relais S se trouve coupé et celui du résonnateur S^2 se trouve complété; mais cette action ne peut être produite entièrement que quand le mouvement de l'armature du relais R^2 a duré un temps suffisant et, de cette manière, les petites oscillations de celle-ci dues aux permutations de polarité ne peuvent exercer une action effective.

En doublant les appareils aux deux stations en correspondance et les disposant comme on le voit sur la figure, de manière à constituer les éléments de combinaisons d'un pont de Wheatstone, c'est-à-dire en plaçant les systèmes transmetteurs à deux des angles opposés du losange, et les appareils récepteurs selon le fil de jonction reliant les deux autres angles, on dispose le système précédent en duplex; mais il faut 1° introduire dans les côtés du losange les rhéostats A, B, A', B'; 2° interposer d'autres rhéostats et condensateurs en X, C, Y, X', C'; 3° introduire quelques dispositions particulières dont nous allons maintenant parler.

Quand on appliqua ce système de transmission sur des lignes d'une grande longueur, on put reconnaître que les effets de démagnétisation du relais R^2, résultant des permutations des polarités de la ligne, se trouvaient grandement augmentés par l'action de la décharge statique, et il en résultait que l'intervention du relais additionnel S ne suffisait plus pour en empêcher l'action sur le résonnateur. Pour y remédier, on dut interposer un rhéostat en X^1 avec une dérivation correspondant à un fort condensateur c et à un second électro-aimant r, réagissant sur une armature placée à l'extrémité du levier-clef du relais R^2 et disposée de manière à ce que les deux actions fussent conspirantes dans le même sens. De cette manière, quand un courant d'une certaine polarité venait à s'annuler, le condensateur se déchargeait immédiatement à travers l'électro-aimant r qui le retenait attiré pendant le temps que le relais R^2 subissait les influences des permutations de polarités contraires.

Dans ce système, les combinaisons de courants sont les suivantes :

1° Quand la première clef est abaissée et la seconde élevée, on a....................	+ 1
2° Quand la seconde clef est abaissée et la première élevée, on a......	− 3 ou − 4
3° Quand les deux clefs sont abaissées..............................	+ 3 ou + 4
4° Quand les deux clefs sont élevées..............................	− 1

« Il résulte de cette disposition, dit M. Prescott, un avantage pratique important et qui est dû à ce fait que les forces requises pour la production des signaux sur les relais polarisés et sur les relais neutres peuvent être réciproquement augmentés ou diminués suivant les besoins, sans aucun inconvénient. Dans certaines circonstances, il arrive même que plus cette différence est grande, meilleurs sont les résultats que l'on obtient, et cela tient à ce que la disposition des combinaisons se rapportant au relais neutre augmente son effet proportionnellement au travail qui lui est demandé. Le rapport des courants respectifs a été varié de 1 à 4 avec des avantages correspondants dans les résultats fournis par la manipulation des appareils. »

Telegraphic Journal July 1. 75

THE QUADRUPLEX TELEGRAPH.*

By F. W. JONES.

Just one hundred years ago George Louis Lesage, of Geneva, constructed a telegraph composed of twenty-four line wires, corresponding to the twenty-four letters of the alphabet, and by the use of frictional electricity and pith balls, succeeded in transmitting intelligible signals over the wires to a distance.

Numberless experiments by different philosophers followed in quick succession with a view of establishing means of rapid communication between widely-separated places, but none of the systems that were devised proved anything more than scientific toys.

It remained for Morse, in 1844, to establish a system which was to stand the test of actual experience.

During the same year considerable activity in experimenting was also manifested in England. The first line of any length was constructed between London and Gosport, on the London and South Western Railway, but it was two years later before lines were extended for commercial purposes.

In our own country, starting with one wire between Baltimore and Washington in 1844, we can now boast miles enough of telegraph wire, owned by the various companies, to encircle the globe about ten times. Chicago had its first wire in 1847, and now the Western Union Chicago office alone works 72 long circuits stretching in every direction to all parts of the country, besides 39 metropolitan and 60 private lines.

So far from adhering to first principles in the use of *twenty-four wires for the transmission of a single message*, the hour is at hand when *twenty-four messages can be transmitted simultaneously over one wire.*

At the present time four messages are sent at the same time a distance of nearly one thousand miles, with the utmost ease and certainty, at the rate of 120 words per minute.

The wonderful instrument performing this miracle in telegraphy is *The Quadruplex*, an invention of Messrs. Prescott and Edison, electricians. It is based on the same principle as the Bridge Duplex, comprising all its main features, and in order to render a description of the Quadruplex easier and more comprehensible, I will briefly review the duplex system. Authors do not agree in their account of the origin of the duplex; some refer it to Dr. Gintl in 1853. It is well established, however, that experiments were made by the Electric Telegraph Company, of England, in 1853, but their system did not prove of any advantage, and it fell into disuse. About the same time Gintl, Siemens, and Frischen directed their efforts towards perfecting a duplex, and many Russian stations were fitted up with their instruments; but, from the fact that no gain was realized over single transmission, the stations were refitted with the ordinary Morse. Mr. De Santy, in 1855, successfully worked the Frischen-Siemens system between Manchester and Altringham. *He only accomplished ten words per minute against sixteen by the single Morse.*

In 1856 attempts were made to work the duplex between London and Birmingham, on the Magnetic Company's wires, and the signals were improved by using a condenser; but the experiments ceased, for the reason that Mr. Gordon, of the firm of R. S. Newall and Co., to whom the English patents belonged, did not deem the addition of condensers of sufficient value to warrant the expense of their construction.

In 1868 the duplex was revived by J. B. Stearns, of Boston, and was actually worked on one of the wires of the Franklin Company. His system, which I will now describe, does not differ materially from those that have preceded it, save in the application of an improved form of double pointed key or transmitter, and, more recently, condensers, whereby long line difficulties were entirely overcome, and the carrying capacity nearly doubled.

A relay is wound throughout with two separate wires, the outer end of one and the inner end of the other are brought directly to the double pointed key. One of the opposite ends of these wires is connected to the line, and the other to a rheostat and ground of resistance equal to the resistance of the line.

The transmitter, or double pointed key, is arranged to be in contact with battery when the lever is depressed, and with ground when elevated—one contact always taking place, through spring contrivances, before the other ceases; thus the line is always on battery or ground.

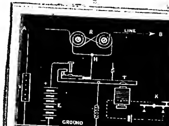
Supposing B, the distant station, to have his key open, the transmitter, which his key opens, keeps the line grounded through one wire of his relay. When Station A closes his transmitter, the current passes therefrom to the relay, and there divides in two directions; one part goes by one coil of the relay to line, and the other part by the second coil of relay to rheostat and ground. The resistances being equal in these two directions, an equal quantity of current flows through them; but, as they pass oppositely around the core no magnetic effect is produced, and the armature is not attracted from the back stop.

The current arriving at station B passes through one coil of his relay to transmitter and ground,

Electrical News aug 19 1875.

Improvements in duplex and multiplex telegraphs. Thomas Alva Edison, of Newark, New Jersey, U.S.A. February 2, 1875.—No. 384. This invention relates to improvements in telegraph instruments and circuits, whereby one wire can be used simultaneously by two operators at both terminal stations, one to send and the other to receive, usually known as a duplex telegraph; also one wire can be simultaneously used by two operators to transmit and two operators to receive at each end, called a quadruplex telegraph. A circuit preserving key brings into operation the whole battery or only a portion to operate one set of electro-magnetic instruments by the rise and fall of tension. Another key reverses the current without breaking the circuit, and a polarised relay magnet responds to the reversal. Rheostats, condensers, and induction-coils are inserted to neutralise static discharges, to equalise and neutralise the action of the currents sent on the receiving instruments at that station, and leave them free to respond to the currents from the distant station; also to establish artificial lines of equal resistance to the main line, and thereby to balance the electrical forces. The polarised relay and differential electro-magnet operate by local circuits the instruments that receive the messages, and indicate the same by sound or marks. At intermediate stations the instruments are arranged so as to work to either terminal station, or by connecting them a relay is effected, so that on long lines the operator at a terminal station works a relay at an intermediate station to send to the distant terminal station, and this is used either in the duplex or quadruplex telegraphs.

Telegraphic Jou



causing his armature to move forward and close the recording sounder. At this moment, should B close his transmitter he will divide his battery between rheostat and line, as was done at A, and feel no effect from it upon his own armature—one part exactly neutralizing the other; but currents being on the line, there is now double the quantity there was when B was open, consequently through the line coil of either relay, there is more current than there is flowing through the rheostat coils; therefore the cores of each relay become magnetized by this difference, and signals are recorded simultaneously at each station.

As soon as the system was tried on long lines a kick was experienced on the armatures, rendering the signals totally unreliable. This was caused by the discharge of return current through relay, and depended for volume on the static capacity of the line. A familiar illustration of this may be had by supposing a straight pipe to connect two points in the same plane, and at one end of the pipe water is forced through at a high pressure; if the pressure is suddenly removed and the pipe left open at each end, part of the water in the tube will return and empty itself, in preference to overcoming the friction of the distant portion of the tube.

Electricity, in a long and well insulated conductor of large metal cross section, will flow through to the distant end and to ground so long as battery contact is maintained; but let the battery be suddenly removed and a ground substituted, part of the charge at that instant left in the conductor will return to ground in preference to passing through the whole resistance of the line to the farther end. This return is the kick that causes so much vexation to telegraphers. By the use of condensers the kick has ceased to annoy, and five hundred mile circuits are now worked as well as those of one hundred.

It will be readily comprehended that the few coils of fine wire of which a rheostat is composed have not the static or charge capacity of a long line, the metal of one weighing only a few ounces, that of the other perhaps a hundred tons of a superior conducting metal, therefore no return charge or kick is felt from the rheostat; but by attaching to the rheostat a condenser whose static capacity is nearly equal that of the line a charge will be returned from it, at the same moment that the battery charge returns from the line, thus destroying all kick in the relay by neutralizing each other's tendency to magnetize the cores.

This system can be worked as well with the *same*

OVER

line and ground, neutralizing all magnetic effect in the cores. Condensers must be used for static discharge the same as in duplex system. The distant station is now asked to dot on positive key, which sends a current attracting the corresponding armature at the home end, closing the local points and recording a signal. Then the distant station dashes on the negative key, closing the armature of home relay at the end opposite the one operated by the positive key, and recording a signal on sounder by contact. When both keys are closed at once the tensions of their batteries are doubled and of positive polarity. This causes a double force to act on the agreeing armature which presses forward a spring, thus closing not only its own sounder, but also the one in the connection with the opposite armature recording signals simultaneously. The weak points of this system seem to lie in the constant and uneven reversals of the current during transmission producing an unsettled condition in the cores; uncertainty of action between the armatures, and the imperfect mechanical contrivance for transferring the operation of the sounder from one tongue of relay to the other.

What may yet come of this system is a problem for future solution. It has worked moderately well on a rheostat circuit of 6,000 ohms, but has disappointed the expectation of its friends on an actual line circuit, probably on account of its infancy and want of a thorough test.

Telegraphic Journal July 1. 75

THE QUADRUPLEX TELEGRAPH.*

By F. W. JONES.

JUST one hundred years ago George Louis Lesage, of Geneva, constructed a telegraph composed of twenty-four line wires, corresponding to the twenty-four letters of the alphabet, and by the use of frictional electricity and pith balls, succeeded in transmitting intelligible signals over the wires to a distance.

Numberless experiments by different philosophers followed in quick succession with a view of establishing means of rapid communication between widely-separated places, but none of the systems that were devised proved anything more than scientific toys.

It remained for Morse, in 1844, to establish a system which was to stand the test of actual experience.

During the same year considerable activity in experimenting was also manifested in England. The first line of any length was constructed between London and Gosport, on the London and South Western Railway, but it was two years later before lines were extended for commercial purposes.

In our own country, starting with one wire between Baltimore and Washington in 1844, we can now boast miles enough of telegraph wire, owned by the various companies, to encircle the globe about ten times. Chicago had its first wire in 1847, and now the Western Union Chicago office alone works 72 long circuits stretching in every direction to all parts of the country, besides 39 metropolitan and 60 private lines.

So far from adhering to first principles in the use of *twenty-four wires for the transmission of a single message*, the hour is at hand when *twenty-four messages can be transmitted simultaneously over one wire*.

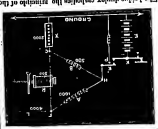
At the present time four messages are sent at the same time a distance of nearly one thousand miles, with the utmost ease and certainty, at the rate of 120 words per minute.

poles of battery ... "agreeing" poles. When both stations send positive currents they neutralize each other on the line side, allowing the currents in the rheostat coils of relays at the home ends to move the relay tongues and record the signals, the same as if both currents combined on the line.

Next in order to the differential duplex comes the bridge duplex, founded on the principle of the Wheatstone Bridge. This method was adapted on the Gibraltar and Lisbon cable in April, 1872, by Mr. De Santy, the electrician of the Eastern Telegraph Company at Gibraltar, at the suggestion of Mr. W. H. Preece, of England.

The length of the cable is 360 nautical miles, and worked by mirror galvanometer and syphon recorder. Mr. De Santy was from March 16th, 1872, until April 11th of same year before he made it a success, so much trouble being felt from the static discharge; this he overcame by making his rheostat circuit similar to the cable in static capacity, dividing his resistance, and interspersing his condensers, so that they would return a proper charge at the exact time it was returning from the cable. Thus he made himself master of the situation, and has since duplexed other cables, including the Mediterranean cable from Gibraltar to Malta.

In the *Journal of the Telegraph*, Sept. 1st, 1873, is described the bridge duplex as a recent invention of J. B. Stearns, of Boston, and as this system is intimately connected with the quadruplex, a brief notice of the former is necessary to make plain the latter.



The bridge duplex embodies the principle of the Wheatstone balance, wherein a current dividing between two circuits, which are connected by a cross wire or bridge, no current will flow over the bridge if the resistances of the circuits on each side of the bridge are equal, or bear the same proportion to each other.

By reference to the diagram it will be seen that when transmitter K is closed the current it sends out will divide at Point H; one part going over line and the other part *via* B and rheostat to ground. Now, if the resistance of these two circuits is equal no current will pass over the bridge wire F C, consequently the relay R will be unmoved. When the current arrives at distant end it divides at F, between the transmitter and rheostat X, in inverse proportion to the resistance of respective routes; the portion passing through F C operates the relay R, and records the signals, producing unequal ... sides of the bridge, causing a current to flow across each bridge and close the relays, recording signals at each end simultaneously.

Towards the close of 1874 it was noised abroad that a quadruplex had been put into successful operation between New York and Boston by Messrs. Prescott and Edison, electricians. More recently it has been put into actual use between New York and Chicago, through a repeater at Buffalo, and between Chicago and Cincinnati — the former distance being nearly one thousand miles, the latter three hundred miles. As previously stated, in the bridge duplex. In the for its formulation the bridge duplex there are two relays—bridge wire of the duplex there are two relays—one is a common relay of very short cores and moderately low resistance, capable of being affected only by strong currents. The other is a Siemens polarized relay, which is sensitive to feeble currents, and is so constructed as to allow the tongue to be thrown on the back or open stop when a current of a certain polarity passes through its coils, and on the front or closing stop when a reverse current passes. There are two separate transmitters brought into use in double transmission from either end. The double transmitter is a pole changer having one spring connected to line and the other to ground. The contacts with each spring are connected crosswise with the smaller portion of main battery through the spring and lever of the single transmitter, which has an additional section of battery inserted between the lever and its closing contact point. When both transmitters are open the smaller part of the battery will be presented to the line. The current flowing therefrom will divide between the sides of the bridge—one part passing to rheostat and earth, the other passing over line and dividing between the bridge wire and the transmitter ground at the receiving end. The portion crossing the bridge will push the tongue of polarized relay on the back stop, but will not affect the common or neutral relay for reasons before stated. If the double transmitter at sending end be closed the same portion of battery is reversed in circuit, deflecting the tongue of polarized relay at distant end to the front or closing stop, thus recording a signal. The second transmitter merely cuts in or out of circuit an increased portion of battery, sufficient to close the distant common relay, and the movements of the first or double transmitter wholly determine the polarity sent to line; when the double transmitter is up and the single one closed the latter cannot record a signal on the polarized relay at the remote station, for the reason that the current is of the wrong polarity; the same effects take place at the home station under similar manipulations at the distant end. Here then is the curious possibility of one operator having his key open, a second his key closed, the third making a dot, and the fourth a dash at the same time, and the respective positions being recognised fully at opposite ends.

Under the supposition that the batteries are divided into proportions of 50 cells and 150 cells the following changes of polarity and quantity will take place on the line during transmission from both stations:—50 plus and 50 minus, 50 plus and 200 minus, 50 plus, 50 plus and 200 plus, 50 minus and 200 plus, 200 minus and 200 plus, 200 minus and 200 minus, 200 plus and 200 plus.

These constant variations and reversals taking place through the relay coils tend to produce in them an unsettled magnetic condition, causing the movements of their armatures to be unsteady and unreliable for signals. To remedy this the bridge wire is supplied with a condenser which is charged by the same currents that work the relays, and so soon as they are withdrawn from relays the condenser discharges before a reversed current reaches them, thus prolonging the signals and preserving a magnetic equilibrium of the cores.

The condensers connected to the equating rheostat require the nicest adjustment to exactly neutralize the static discharge from line. Compared with the differential system the percentage of effective signalling current on the quadruplex is very low, and is divided between two relays in the same circuit, therefore the utmost care is necessary in balancing and arranging the different adjustments to bring out its full value. During actual service it requires great vigilance and an intelligent supervision, else it will fail to even duplex the capacity of a wire. When depended on to do the work of four wires it will be readily seen how grave would be the smallest delay, hence it behoves managers to familiarize themselves thoroughly with every part, in order to render the proper service of the quadruplex to the companies by whom they are employed.

Other methods of quadruplexy have been devised, but have proved of no practical value. That of M. Meyer, of the French Telegraph administration, exhibited at the Vienna Exposition, is the most notable, transmitting four messages over one wire in the *same* direction, but its best performance was only 110 ordinary messages per hour. Dr. H. C. Nicholson, of Mt. Washington, near Cincinnati, has also constructed a quadruplex for transmitting two messages in opposite directions over one wire at the same time. His system is on the differential principle. The outgoing currents passing in opposite directions around the home relay produce no effect on its cores. Two keys are used and are so arranged as to send current to line in the following order: When one key is depressed a positive current of given tension, when the other is closed a negative current of equal tension; when both keys are closed simultaneously a positive current of double the tension of that sent by a single key.

The relay has horizontally, and side by side, two straight cores wound differentially, and at either end are permanently magnetised armatures. One is placed horizontally on a tongue in front of the poles at one end, and the other armature swings vertically on an axis between two semi-circular extensions of the poles opposite those facing the first described armature. Both armatures are so polarized that when one is attracted by a current of certain polarity passing through the coils the other is repelled. In order to balance for work, the distant station is asked to open both keys. This removes his batteries and grounds the line through his instruments. At the home station dots are struck on either key, and the equating rheostat is so adjusted that an even division of current is made through the relay between ... the expectation of its friends on an actual line circuit, probably on account of its infancy and want of a thorough test.

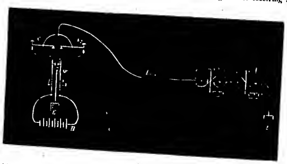
Electrical News aug 19 1875.

Improvements in duplex and multiplex telegraphs. Thomas Alva Edison, of Newark, New Jersey, U.S.A. February 2, 1875.—No. 384. This invention relates to improvements in telegraph instruments and circuits, whereby one wire can be used simultaneously by two operators at both terminal stations, one to send and the other to receive, usually known as a duplex telegraph; also one wire can be simultaneously used by two operators to transmit and two operators to receive at each end, called a quadruplex telegraph. A circuit preserving key brings into operation the whole battery or only a portion to operate one set of electro-magnetic instruments by the rise and fall of tension. Another key reverses the current without breaking the circuit, and a polarised relay magnet responds to the reversal. Rheostats, condensers, and induction-coils are inserted to neutralise static discharges, to equalise and neutralise the action of the currents sent on the receiving instruments at that station, and leave them free to respond to the currents from the distant station; also to establish artificial lines of equal resistance to the main line, and thereby to balance the electrical forces. The polarised relay and differential electro-magnet operate by local circuits the instruments that receive the messages, and indicate the same by sound or marks. At intermediate stations the instruments are arranged so as to work to either terminal station, or by connecting them a relay is effected, so that on long lines the operator at a terminal station works a relay at an intermediate station to send to the distant terminal station, and this is used either in the duplex or quadruplex telegraphs.

10 12

SIEUR'S DOUBLE TRANSMISSION TELEGRAPH SYSTEM.

THE principle of this system is shown by the figure l_1 and l_2, are spring contact levers connected to the poles of a battery B. These levers normally make



contact with stops connected with the front contacts of keys K_1 and K_2. A cam C, connected to earth, is kept in very rapid rotation by means of clockwork, and the levers, by this means, are caused to oscillate alternately, with extreme rapidity, to and fro from their contact stops. The result of this arrangement is, that if key K_1 is depressed, a rapid succession of currents of one sign are caused to pass out to line; and if K_2 be depressed, a rapid succession of currents of the opposite sign pass to line; whilst if both keys be depressed, then both positive and negative currents succeeding one another with great speed, will flow.

The line wire leads to a pair of polarised relays R_1 and R_2 so connected up, that one responds to positive and the other to negative currents, each operating a local battery connected with receiving instruments I_1, I_2.

As the positive and negative currents alternate, the one set of signals does not interfere with the other set, and as the succession of impulses of either sign is rapid, the effect on each receiver does not practically differ from that produced by a continued current of the sign for which the receiver is adapted.

Several modifications of the arrangement just described are proposed by M. Sieur; thus, the relay tongues may normally be held over to their insulating stops by the succession of currents, the depression of the keys being made to cut off the currents of either sign. The receiving apparatus also, may be a single relay provided with two tongues oppositely polarised. Again, two batteries may be employed to give the opposite currents, the cam in this case putting earth on to each battery alternately; indeed, the modifications of which the principle is susceptible are very numerous, as must be evident.

By duplexing the arrangement in the ordinary way, quadruplex working is obtained.

We understand that M. Sieur's system is in successful operation on the Continent.

The apparatus is shown in the Telegraphic Annexe of the Paris Exhibition.

13

~~which case of course the height of the water in the tube would not be a true measure of the strain on the wire under test. With this instrument tests can be made very rapidly, as the breaking strains are read off in pounds from a scale attached to the glass tube. The results are also obtained with great accuracy, as the instrument cannot possibly get out of order.~~

~~Of course there is nothing new in the principle of this apparatus, as it is simply that of the old hydrostatic bellows.~~

~~The elongation is measured thus:—A small scale is attached at its one extremity to the piece of wire under test, and near its other extremity there is attached to the wire a small pointer, which moves over the scale as the wire stretches. This is much better than measuring, as is frequently done, the distance between the clamps before and after testing, as this latter method frequently gives erroneous results from the slipping of the wire in the clamps~~

MULTIPLE TRANSMISSION BY THE SAME WIRE.

By M. MAYER,
Of the French Telegraph Administration.

THIS system of apparatus, based on the division of work, has for its end the utilisation of all the currents which in a given time can be made to succeed each other in a wire, so that several *employés*, each sending twenty to thirty messages per hour, may transmit them by the same wire, as is now effected by separate wires.—that is to say, each can, at will, receive or transmit, or rest; each can at any instant interrupt the transmission of his correspondent, without the least inconvenience to his neighbours. This may be attained without detriment to the methods ordinarily in use; and whilst the number of *employés* remains the same, the number of wires is reduced for the same amount of work. It may be accepted as a principle that the system reducing the number of wires to the least possible is the system showing the greatest progress.

The number of transmissions that a telegraph line will carry varies naturally with its conductibility. It is generally admitted that with a speed of twenty-five messages per hour, on a Morse instrument, about five emissions of the current occur per second. Consequently, n being the sum of the currents which in a second can succeed each other in a conductor, $\frac{n}{5}$ represents the number of receivers which it is possible to establish upon a single wire, or the number of *employés* that can work at the same time. The multiple apparatus about to be described is constructed for four transmissions, and is served by four clerks. It revolves with a velocity of 75 turns per minute, presenting four letters at each turn. It records 100 messages in the hour, with 20 emissions of the current per second. This is less than a maximum result; for we learn by experience that all telegraph lines admit of many more than 20 emissions per second, to about a maximum of 500 per second.

As the apparatus is arranged for transmission, four keys are placed with their receivers upon a table, each receiver having its paper band. The printing arrangement is a quarter-spiral on which

(over)

longated spiral. The helix of the receiver and he rubbing-contact of the distributer make their evolutions in the same time. An inking-wheel evolves freely on each of the helices. The letters ppear transversely upon the paper band (*i.e.*, at ight angles to the ordinary Morse characters), the aper being raised to the writing-helix by the arature of the electro-magnet over which it passes. This transversal disposition of the letters presents double advantage: it avoids confusion between onsecutive letters, and reduces considerably the ength of the paper band used for each dispatch.

The multiple transmission, then, depends upon he identical revolutions in the same time of certain portions of the apparatus at distant stations. This s effected by the aid of a conical pendulum and a egulating system, by which a correcting current is ransmitted every second. Further, it is arranged hat the line should be put to earth at both extremities after each emission of the current.

The apparatus has been in use for some time in rance, between Paris and Lyons, every day from o'clock in the morning until 6 in the evening, under the direction of an official Commission, with he following results:—The maximum per operator has been 28 messages per hour, with a maximum or the four operators of 110 messages the hour: while a Morse gives only 18 messages per line, and Hughes' type printer 22 messages the hour. And hat relatively the work done by this apparatus is o that of the Morse as 4 : 1, and of the Hughes is 2 : 1.

A multiple transmitter is shown in action at the Vienna Exhibition this year.

Simultaneous Transmission.—[M. Wenckebach, an old telegraph engineer, has made the following communication to the *Journal Telegraphique* as a resolution of the problem of simultaneous transmission. As the solution indicated by the author is entirely theoretical, and has not been confirmed by experiment, the paper is published as an idea susceptible of enlargement.]—Many have sought more simple means of double transmission. I have also sought this solution, but by an entirely different process. It is a generally known fact that frictional electricity is propagated along an insulated conductor, in which, at the same time, a galvanic current is passing. This consideration has led me to utilise this kind of electricity. Consequently I have connected one of the extremities of the line to a Morse apparatus, and the other to an ordinary electrical machine and Leyden jar, with the idea that the sparks produced would pierce the band of paper. The frictional electricity might be made to pass to the printing point direct, and prevented circulating around the electro-magnet.

[This idea has been superseded by several English inventors, and at best is a clumsy contrivance.—ED.]

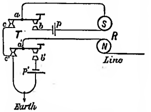
DESCRIPTION OF A SYSTEM OF SIMULTANEOUS TRANSMISSION IN OPPOSITE DIRECTIONS.

By M. GIOVANNI MARINI,
Of the Italian Telegraphic Administration.

The system of double transmission that I am about to describe is based upon the following principles:—A relay with two bobbins is fixed to a permanent magnet in such a way that the armature acts by repulsion, and not by attraction. The wire of one of the bobbins is distinct from the wire of the other bobbin, and the two wires thus form two distinct circuits—the one a local circuit, the other a line circuit. The soft iron cores of these two bobbins of the relay are fixed, the one to the north pole, and the other to the south pole of a permanent magnet. The transmitting key is of the ordinary Morse form very slightly modified; to the front part of it two contacts insulated from one another are added, which serve for the two circuits above mentioned. These contacts should be so adjusted that by the movement of the key they should make or break contact exactly at the same moment.



The fig. represents the arrangement of this system of double transmission. R represents the relay, N the bobbin with the north pole, S the bobbin with the south pole, T the double key, *a* and *a'* the two levers of the key, formed of little flat springs, to which springs the two outer ends of the wires of the bobbins are connected; *c* and *c'* are two metallic contacts fixed at the extremities of the levers and in connection with the earth. In the normal position of this double key the levers rest on these contacts, and are thus in connection with the earth; *b* and *b'* are two little metallic plates connected to the positive poles of two batteries—the local battery *p*, and the line battery *p'*. The connections being thus arranged, the following results are obtained:—

It is first of all necessary that the strength of the local battery, which sends a current through the south pole bobbin, be so regulated that it may transmit a current exactly equal in power to the one sent out by the line battery through the wire of the other bobbin and out to line to the corresponding instrument at the further station. This equality can be arrived at by observing the deviations given by a good galvanometer, which can be switched either into the line or the local circuit—the battery of the latter being varied, so that the deflections in both cases are the same. When the batteries are in good condition this equilibrium may be maintained for several days unless accidental circumstances interfere.

For a line of a given resistance the relation between the local and line batteries is in the proportion of about 1 to 8. If, now, the key at one station be depressed, the levers *a a'* are put simultaneously in communication with the contacts *b b'*; and at the same instant the communication of the levers *c c'* with the earth is interrupted. The current of the local battery *p* traverses the south pole bobbins to get to earth, and produces in the soft iron core a contrary magnetism to that which is given it by the permanent magnet; that is to say, the current tends to diminish the attractive force of the core for the armature; but, at the same time, the current of the line battery *p'* traverses the north pole bobbin, and out to line, and increases the attractive power of the core of that bobbin; for at the transmitting station this current produces in the soft iron core a magnetism equal to that which the local battery takes away, consequently the armature remains attracted against the poles.

At the other station, the arrival current entering by the outer extremity of the wire of the north pole bobbin, goes to earth through the lever *a'* and the contact *c'*, and produces in the soft iron core a magnetism contrary to that which is given it by the permanent magnet; the attractive force on the armature being thus diminished, the armature rises off the poles under the influence of an antagonistic spring. Immediately on the cessation of the current the core regains its magnetism, and the armature is again attracted.

Finally, if the keys at both stations are simultaneously depressed, the currents going out to line being equal and contrary, annul one another, and thus the north pole bobbins of the two relays are not influenced by the currents. The south pole cores, then, being both under the influence of the local batteries, have their magnetic powers diminished, and the armatures at both stations consequently rise.

If in this last position one station allows his key to rise, the current from that station ceases to be emitted by him; but the connection of the line wire to earth is not interrupted, and the armature, though no longer under the influence of the local current, but under the influence of the current from

Vol. V.—No. 101.

QUADRUPLEX TELEGRAPHY.

We are not aware that a quadruplex circuit exists in England at present, although we are assured that since 1874 quadruplex telegraphy has been an established fact in America, and that its employment there has been eminently successful. Statistics are nevertheless wanting to establish its practical value; and, notwithstanding the valuable communication by Mr. G. B. Prescott, read before the Society of Telegraph Engineers at their last meeting, we seem to be still as much in the dark as ever as to the real advantages of quadruplex telegraphy. Without entering at all minutely into the system, it is sufficient to state that the difficulties inherent to the adoption of quadruplex telegraphy are greater than at first sight would be imagined. As a scientific problem, its success cannot be questioned. From the days when Gintl demonstrated the possibility of sending two communications in opposite directions simultaneously on the same wire, and Stark and Bosscha showed that the same thing might be done in the same direction on the same wire, quadruplex telegraphy, or, for the matter of that, theoretically, any multiple telegraphy, may be said to have been established. But for twenty years this appears to have remained a barren scientific fact; and it was not until the impulse given to further investigation in the field of duplex telegraphy by the successful labours of Stearns drew forth again the quadruplex question, that its practical introduction was seriously thought of. To America, unquestionably, belongs the credit of having revived the question, and, so far as we can judge, of having solved it with at least some degree of success. It is well to recognise and admit this fact, for in these days of fierce competition the rival claims set up by different countries for the introduction of anything that is new would undoubtedly soon extend to quadruplex telegraphy as well.

Quadruplex telegraphy being admitted as a scientific fact, there arises the question of to what extent is it likewise a practical success—in other words, what saving in money is actually effected by its introduction, for to this narrow limit all practical successes must eventually reduce themselves. On this point, as we have stated at the outset, statistics are unfortunately wanting; and, consequently, we are unable to form any opinion on the subject. It may, however, be well to remark, what was pointed out by Mr. Kempe the other evening, that the *primâ facie* case is not all upon one side. Quadruplex telegraphy, judging from the extremely elaborate and intricate diagrams which illustrated Mr. Prescott's paper, means very nice adjustment and consequent liability to derangement. If this is to be kept in order, intelligent and well-trained—which means at the same time comparatively highly paid—labour must be employed. We cannot say how far this applies to the United States. It is often urged that the technical training of the staff in the details of their apparatus is so well looked after there that little trouble is experienced with that comparatively fruitful source of trouble in every other country—adjustment.

Then, again, the reduced carrying power of the wire is a factor which ought not to be lost sight of. Rival inventors of duplex systems are often heard to urge that by employing their particular system the working becomes an easier matter than when the line is worked singly. We shall not be surprised to hear the same assertion made about the quadruplex system, although on the face of it there appears to be nothing to support the assertion, but, on the contrary, every reason against it, even so far as duplex telegraphy is concerned. Furthermore, working a quadruplex system—that is, four circuits upon one wire—to meet the requirements of busy centres of commerce, looks very much like entrusting too many of the eggs to one basket, and in the event of interruptions could not fail to be attended with the most serious inconvenience.

Mr. Preece very wisely, we think, in the discussion which followed the reading of Mr. Prescott's paper, refrained from saying a single word either way until he had had an opportunity of examining personally for himself and forming on the spot an opinion as to the value of the quadruplex system. Mr. Preece and his fellow-commissioner, Mr. Fischer, leave for America to-day, and not the least interesting fact that they will have to tell on their return will be what they find to be the true value of quadruplex telegraphy.

ON A NEW SYSTEM OF DUPLEX TELEGRAPHY.

By J. J. FAHIE, Assoc. Soc. Tel. Engineers.

This system is based upon two very simple facts, as follows:—

1st. When, in an arrangement such as that shown in fig. 1, the resistances A, B, E, and R are proportional, that is when

$$\frac{A}{B} = \frac{E}{R}$$

earth may be applied at the point P without affecting the deflection of the galvanometer needle G.

Employment of the Tuning Fork in Electric Telegraphy.—M. La Cour.—In ordinary telegraphy only two simple signals are produced, either by opposite currents, or by prolonging, more or less, the duration of one current. M. La Cour produces a great number of simple signals with one wire. A tuning fork is caused to open and close an electric circuit at each vibration; and these pulsations of current act electro-magnetically on a second fork in unison with the first, putting it in vibration. In this receiving instrument, the branches of the fork are each enclosed (with freedom for oscillation) in a bobbin; the bobbins receive the intermittent current, which then passes to an electro-magnet so placed that its two poles are close to the two opposite poles produced in the branch-extremities of the fork. Thus the current produces an attraction (when it passes), which opens the branches of the fork; when it ceases, the branches approach each other, and so on repeatedly. The vibrations quickly reach such an amplitude that one branch touches a slip of metal, closing the circuit of a local battery and giving a signal. The intermittent current makes only that fork speak which is in unison with the sounding fork. Thus, with a number of different forks at one station, and an equal number of receivers corresponding, we may produce an equal number of simple signals, each requiring only a simple movement; and each signal corresponding to a letter, figure, &c., dispatches may be sent more quickly than by the ordinary method. A signal may be sent to one of several stations without the others perceiving it. Several signals can be produced simultaneously by the same wire. Other advantages may suggest themselves.

17

ON QUADRUPLEX TELEGRAPHY.*

By F. L. POPE.

(From the *Journal of the Telegraph*.)

The simultaneous transmission of two telegraphic communications in opposite directions upon the same wire, now known by the name of duplex telegraphy, dates back to the year 1853. The first to conceive of its possibility, as well as the first to carry the conception into practical effect, was Dr. Wilhelm Gintl, Director of State Telegraphs in Vienna, Austria. He described his method in a paper read by him before the Vienna Academy of Sciences on the 9th of June, 1853, and in July of the same year, it was put in practical operation between Prague and Vienna.

In March of the following year, Carl Frischen, a telegraphic engineer of Hanover, Germany, im-

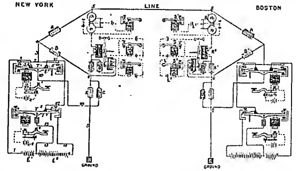
uestionably the
h has been made
of its original
e of the addition
1872. Frischen
ces composed of
an artificial or
the main line,
this day. His
made between
h of May, 1855.

The labors of Frischen and of Siemens and Halske of Berlin, who during the same year, independently but subsequently worked out a method almost precisely similar to Frischen's, brought the system of simultaneous transmission in opposite directions to a state of perfection which answered a very good purpose upon the comparatively short

applicable either to a single or a double telegraph in one direction. In the first published description of his method, dated at Vienna, October 31, 1855, Stark concludes as follows:

"With the method of double transmission in the same direction, we may also combine that of counter-transmission (*gegensprechen*), and hence arises the possibility of simultaneously exchanging four messages upon one wire between two stations, which will however hardly find any application in practice."* This is unquestionably the earliest published suggestion of what is now known as the quadruplex system.

Dr. Bosscha, in a description of his system read before the Royal Academy of Sciences of Holland, on the 27th of October, 1855, and published in Transactions, vol. iv. p. 101, not only makes the same suggestion, but sets forth in detail a method of accomplishing the result. Having described his method of double transmission in the same direction he says: "Now, if we wind each of the receiving relays with two wires, and divide the



lines, and at the slow rate of transmission in vogue at that day.

The success of these ingenious inventions gave an entirely new direction to the minds of the host of enterprising electricians on the continent of Europe, and during the following year, 1855, the problem of simultaneous transmission in the same direction, which naturally suggested itself as the next step in the progress of invention, was solved with more or less success by the independent labours of Dr. J. B. Stark of Vienna, Dr. Werner Siemens, Dr. August Kramer and A. Bernstein, of Berlin, and Dr. J. Bosscha Jr., of Leyden; each of these inventors having published a full account of his method in the latter part of 1855 and the early part of 1856. At least two of them, Stark and Bosscha, clearly saw that the successful solution of the difficult problem of simultaneous transmission in the same direction included as a necessary consequence the solution of the problem of quadruple transmission also; for a knowledge of the invention of Gintl as perfected by Frischen, was all that was needed to show that it was equally

current at the sending station according to the plan of Siemens and Halske (Frischen) through the two coils of the home relay in opposite directions, then it becomes practicable for both stations to transmit at the same moment without their own relays being affected by their own transmitted currents, and in this manner it is possible to send four signals simultaneously through one wire. This solves the problem in its largest generality."

Thus Stark and Bosscha, as early as 1855, both recognised the indisputable fact, that the production of a successful method of quadruplex transmission depended solely upon the successful solution of the problem of double transmission in the same direction. If this could be accomplished, it becomes a mere matter of mechanical detail to combine with it Frischen's or any other system of counter-transmission.

It has been stated that methods of double transmission in the same direction were worked out independently, but almost coincidently, by a

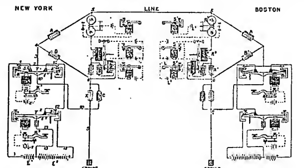
proved upon Gintl's plan, by making use of a branch current from the main battery for compensating the effect of the outgoing current upon the home relay, instead of the local current employed by Gintl. This is unquestionably the most important improvement which has been made in duplex telegraphy from the time of its original invention by Gintl, down to the time of the addition of the condenser by Stearns, in 1872. Frischen used a differential relay having helices composed of two equal and opposing wires, and an artificial or rheostat line equal in resistance to the main line, substantially as they are used at this day. His first practical experiment was made between Hanover and Gottingen on the 26th of May, 1855.

The labors of Frischen, and of Siemens and Halske of Berlin, who during the same year, independently but subsequently worked out a method almost precisely similar to Frischen's, brought the system of simultaneous transmission in opposite directions to a state of perfection which answered a very good purpose upon the comparatively short

applicable either to a single or a double telegraph in one direction. In the first published description of his method, dated at Vienna, October 31, 1855, Stark concludes as follows:

"With the method of double transmission in the same direction, we may also combine that of counter-transmission (*gegensprechen*), and hence arises the possibility of simultaneously exchanging four messages upon one wire between two stations, which will however hardly find any application in practice."* This is unquestionably the earliest published suggestion of what is now known as the quadruplex system.

Dr. Bosscha, in a description of his system read before the Royal Academy of Sciences of Holland, on the 27th of October, 1855, and published in Transactions, vol. iv. p. 101, not only makes the same suggestion, but sets forth in detail a method of accomplishing the result. Having described his method of double transmission in the same direction he says: "Now, if we wind each of the receiving relays with two wires, and divide the



lines, and at the slow rate of transmission in vogue at that day.

The success of these ingenious inventions gave an entirely new direction to the minds of the host of enterprising electricians on the continent of Europe, and during the following year, 1855, the problem of simultaneous transmission in the same direction, which naturally suggested itself as the next step in the progress of invention, was solved with more or less success by the independent labours of Dr. J. B. Stark of Vienna, Dr. Werner Siemens, Dr. August Kramer and A. Bernstein, of Berlin, and Dr. J. Bosscha Jr., of Leyden; each of these inventors having published a full account of his method in the latter part of 1855 and the early part of 1856. At least two of them, Stark and Bosscha, clearly saw that the successful solution of the difficult problem of simultaneous transmission in the same direction included as a necessary consequence the solution of the problem of quadruple transmission also; for a knowledge of the invention of Gintl as perfected by Frischen, was all that was needed to show that it was equally

current at the sending station according to the plan of Siemens and Halske (Frischen) through the two coils of the home relay in opposite directions, then it becomes practicable for both stations to transmit at the same moment without their own relays being affected by their own transmitted currents, and in this manner it is possible to send four signals simultaneously through one wire. This solves the problem in its largest generality."

Thus Stark and Bosscha, as early as 1855, both recognised the indisputable fact, that the production of a successful method of quadruplex transmission depended solely upon the successful solution of the problem of double transmission in the same direction. If this could be accomplished, it becomes a mere matter of mechanical detail to combine with it Frischen's or any other system of counter-transmission.

It has been stated that methods of double transmission in the same direction were worked out independently, but almost coincidently, by a

Employment of the Tuning Fork in Electric Telegraphy.—M. La Cour.—In ordinary telegraphy only two simple signals are produced, either by opposite currents, or by prolonging, more or less, the duration of one current. M. La Cour produces a great number of simple signals with one wire. A tuning fork is caused to open and close an electric circuit at each vibration, and these pulsations of current act electro-magnetically on a second fork in unison with the first, putting it in vibration. In this receiving instrument, the branches of the fork are each enclosed (with freedom for oscillation) in a bobbin; the bobbins receive the intermittent current, which then passes to an electro-magnet so placed that its two poles are close to the two opposite poles produced in the branch-extremities of the fork. Thus there is produced an attraction (when it passes), which opens the branches of the fork; when it ceases, the branches approach each other, and so on repeatedly. The vibrations quickly reach such an amplitude that one branch touches a slip of metal, closing the circuit of a local battery, and giving a signal. The intermittent current makes only that fork speak which is in unison with the sounding fork. Thus, with a number of different forks at one station, and an equal number of receivers corresponding, we may produce an equal number of simple signals, each representing only a simple movement; and each signal corresponding to a letter, figure, &c., dispatches may be sent as quickly than by the ordinary method. A signal may be sent to one of several stations without the others perceiving it. Several signals can be produced simultaneously on the same wire. Other advantages may suggest themselves.

... News

number of inventors during the year 1855. The ingenious and active German electricians, recognizing that the accomplishment of this result was the key to simultaneous quadruplex transmission, had diligently laboured at the problem. Let us now consider the results of their labours.

In any system of simultaneous double transmission in the same direction, two keys are required at the sending station, and at least four different electrical conditions of the line must be provided for, one for each of the four following cases:

1. When the first key is closed and the second key open.
2. When the second key is closed and the first key open.
3. When both keys are closed.
4. When both keys are open.

The methods of Stark, Siemens, and Bernstein (No. 1), though varying in detail, were arranged upon one general principle, the four electrical conditions of the line being as follows:

1. A positive current having a strength of 1.
2. A positive current having a strength of 2.
3. A positive current having a strength of 3.
4. No current.

The methods of Bernstein (No. 2), Bosscha, and Kramer, and at a later date those of Schreder (1860), and Maron (1862), were arranged upon another and better principle, as follows:

1. A positive current having a strength of 1.
2. A negative current having a strength of 2.
3. A positive (or negative) current having a strength of 2.
4. No current.

There are two serious difficulties, leaving minor ones out of consideration, which are inherent in every system of simultaneous double transmission in the same direction. In the first place, when either key is passing from its front to its rear contact, it causes a momentary interruption of the signal which is at the same time being transmitted by the other key. Neither Stark nor Siemens suggested any means of overcoming this difficulty. Bosscha and Kramer made use of a device originally invented by Gintl,* viz., that of keeping the battery constantly in the main circuit, but shunted by the key, so that when the latter was depressed the short circuit was broken and the current flowed to line, but when raised the battery was again short-circuited. This plan effectually disposed of the difficulty in question, but was injurious in its effect upon the batteries. Bernstein, however, hit upon the method now in use, that of providing each of his keys with a spring, so arranged as to close the front contact at or before the time of interrupting the rear contact. This difficulty was, therefore, effectually removed as early as 1855. The second difficulty is a still more serious one, and arises in the following manner: In the simultaneous operation of the apparatus there must, of necessity, frequently be a change from a positive to a negative condition, or *vice versa*, of the line, and of the relays or receiving instruments, consequent upon the movement of a single key; yet it is evident that the reversal of the magnetic polarity of a receiving instrument by the action of one key must interfere with a signal which is being given upon it at the same time by the action of the other key. This difficulty is met with, in some form, in every arrangement of the receiving instruments. Stark employed three neutral relays adjusted to varying degrees of sensitiveness in one arrangement, and two polarized and one neutral relay in another, as also did Bosscha and Kramer. Bernstein used a single relay with three armatures of varying adjustment. Neither Stark nor Siemens suggested any method of remedying this serious defect, and judging from his published paper on the subject, the latter evidently considered it an insurmountable one. Bosscha, Bernstein, and Kramer, by making use of different modifications of the same principle, that of operating the recording instrument or sounder by the opening of a shunt circuit, as the first and last had already done with the main batteries, and by working from the rear instead of the front contact of the receiving relay, theoretically succeeded in surmounting this obstacle. Practically, however, the method of operating a register or sounder by closing and breaking a shunt, is a very unsatisfactory one. It not only exhausts the local battery with great rapidity, but the demagnetization of the iron cores takes place with far less rapidity when the battery is cut off by a shunt even of very small resistance, than when it is completely interrupted by breaking the circuit in the usual way, and this renders it impossible to receive and record the telegraphic signals with the rapidity that is necessary in modern telegraphy.

When these methods came to be tried on lines of a length exceeding 100 or 150 miles, the interference of the static discharges was superadded to the already existing difficulties, and for these reasons the results were on the whole so unsatisfactory that the subject remained in abeyance for many years. The subsequent labors of Schreder, Wartmann, Maron, Schaak, and Zetsche, between 1855 and 1865, though exhibiting great ingenuity and research, added little or nothing of practical value to what had already been done by the earlier inventors in the same field.

The revival of the duplex system in America, and its extensive introduction into practical use, both in this country and in Europe, resulting from the improvements of Joseph B. Stearns,—notably his method of compensating the effects of the static discharge from the line by the application of the condenser, which was made known in the winter of 1871-2—once more turned the attention of electricians to the problem of simultaneous transmission in the same direction.

In a paper published in the *Philosophical Magazine* of June, 1873, Oliver Heaviside, of Newcastle-on-Tyne, England, pointed out, as Stark and Bosscha had done before him, that the invention of a system of simultaneous transmission in the same direction furnished at the same time the solution of the problem of quadruple transmission. He says: "It is theoretically possible to send any number of messages whatever simultaneously in one and the same direction upon a single wire. Now by combination with a null duplex system it becomes obviously possible to send any number of messages in the other direction while the opposite correspondences are going on, and without interference. Thus the working capacities of telegraphic circuits may be increased indefinitely by suitable arrangements. * * * From experiments I

* Dub's Journal, II. 135.

have made I find it is not at all a difficult matter to carry on four correspondences at the same time, namely, two in each direction, and if we may suppose the growth of telegraphy will be as rapid in the future as it has been in the past, it seems not improbable that multi-telegraphy will become an established fact."

During the summer of 1874, T. A. Edison, of Newark, N. J., while engaged in conjunction with George B. Prescot, electrician of the Western Union Telegraph Company of New York, in experimenting upon Stearns's duplex apparatus with a view of introducing certain modifications and improvements therein, devised a system of simultaneous transmission in the same direction which differed materially in principle from any of its predecessors, and which was destined to furnish the basis of the first practical solution of the curious and interesting problem of quadruplex telegraphy.

The distinguishing principle of this method consists in combining together two distinct and unlike methods of single transmission, in such a manner that they may be carried on independently upon the same wire, and at the same time without interfering with each other. One of these methods of single transmission is used principally in England, where it is known as the double-current system, and the other is the single-current or open circuit system, used on the continent of Europe. In the double-current system the battery remains constantly in connection with the line at the sending station, its polarity being completely reversed at the beginning and at the end of every signal without breaking the circuit. The receiving relay is provided with a polarized or permanently magnetic armature, but has no adjusting spring, and its action depends solely upon the reversals of polarity upon the line, without reference to the strength of the current. In the single-current system, on the other hand, the transmission is effected by closing and breaking, or increasing and decreasing the current, while the relay has a neutral or soft iron armature, provided with a retracting spring. In this system the action depends solely upon the strength of the current, its polarity being altogether a matter of indifference.

It will therefore be apparent that by making use of these two distinct qualities of the current, viz., polarity and strength, two sets of instruments may be operated, at the same time, on the same wire. This method possesses, moreover, the important practical advantage that the action of each of the two receiving relays is perfectly independent. Each receiving operator controls his own relay and can adjust it to suit himself without interfering with the other, a peculiarity that none of the former methods possessed. As soon as this method was practically worked out, it became at once obvious that any of the different methods of simultaneous transmission in opposite directions already in use might be applied to it, as Stark, Bosscha, and others had long ago pointed out, the result of which would be a practical system of quadruplex transmission. This was shortly afterwards done upon the lines of the Western Union Telegraph Company between New York and Boston, a distance of 240 miles, and both the bridge and the differential system of duplex working were tried in combination with it, with excellent results. When, however, the apparatus was experimentally tested on a circuit of about 450 miles, the effects of static induction became very strongly marked, and it was found that these could be more conveniently compensated in the bridge than in the differential system. The former was, therefore, decided upon as being better suited to the usually existing conditions than the latter.

The diagram shows the quadruplex apparatus as arranged upon the bridge plan.

t^1 is a double current transmitter or pole-changer, operated by an electro-magnet, local battery e^1, and finger key k^1, in a manner well understood. The office of the transmitter t^1 is simply to interchange the poles of the main battery E_1 with respect to the line and ground wires, whenever the key K_1 is depressed; or, in other words, to reverse the polarity of the current upon the line by reversing the poles of battery E_1. By the use of properly arranged spring contacts s_1 s_2, this is done without at any time interrupting the circuit. Thus the movements of the transmitter t^1 cannot alter the strength of the current sent out to the line, but only its polarity or direction. The second transmitter t^2 is operated by a local circuit and key K^2 in the same manner. It is connected with the battery wire 12, of the transmitter t^1 in such a way that when the key K^2 is depressed, the battery E^1 is enlarged by the addition of a second battery E^2 of two to three times the number of cells, by means of which it is enabled to send a current to the line of three or four times the original strength, but the polarity of the current with respect to the line of course still remains as before, under control of the first transmitter t^1.

At the other end of the line are the two receiving instruments R^1 and R^2. R^1 is a polarized relay with the permanently magnetic armature, which is deflected in one direction by positive, and in the other by negative currents, without reference to their strength. This relay consequently responds solely to the movements of key K^1, and operates the sounder S_1, by a local circuit from battery L_1 in the usual manner. Relay R^2 is placed in the same main circuit, and is provided with neutral or soft iron armature, and responds with equal readiness to currents of either polarity, provided they are strong enough to induce sufficient magnetism in its cores to overcome the tension of the opposing armature-spring. The latter, however, is so adjusted that its retractile force exceeds the magnetic attraction induced by the current of the battery E_1, but is easily overpowered by that of the current from E_1 and E_2 combined, which is three or four times as great. Therefore, the relay R^2 responds only to the movements of of key K^2 and transmitter t^2.

The same difficulty which had baffled former inventors arises, however, in this connection. When the polarity of the current upon the line is reversed during the time in which the armature of R^2 is attracted to its poles, the armature will fall off for an instant, owing to the cessation of all attractive force at the instant when the change of polarity is actually taking place, and this would confuse the signals by false breaks if the sounder were connected in the ordinary way. By the arrangement shown in the figure, the armature of the relay R^1 makes contact on its back stop,* and a

second local battery L, operates the receiving sounder S_2. Thus it will be understood that when relay R^2 attracts its armature, the local circuit of sounder S_2 will be closed by the back contact of local relay S; but if the armature of R^2 falls off it must reach its back contact, and remain there long enough to complete the circuit through the local relay S, and operate it, before the sounder S_2 will be affected. But the interval of no magnetism in the relay R^2, at the change of polarity, is too brief to permit its armature to remain on its back contact long enough to affect the local relay S, and through the agency of this ingenious device the signals from K_2 are properly responded to by the movements of sounder S_2.

By placing the two receiving instruments R and R_1 in the bridge wire of a "Wheatstone balance," according to Stearns's patent of Nov. 12, 1872, and duplicating the entire apparatus at each end of the line, the currents transmitted at either station do not affect the receiving instruments at that station. Thus in figure 1 the keys K_1 and K_2 are supposed to be at New York, and their movements are responded to only by the receiving relays R_1 and R_2 at Boston. The duplicate parts which are not lettered operate precisely in the same manner, but in the opposite direction with respect to the line.

In applying this system of quadruplex transmission upon lines of considerable length, it was found that the interval of no magnetism in the receiving relay R^2 (which, as above stated, takes place at every reversal of the polarity of the line current), was greatly lengthened by the action of the static discharge from the line, so that the contrivance of the local relay S was not sufficient to overcome the difficulties arising therefrom. A rheostat or resistance, X_1, was therefore placed in the bridge-wire with the receiving instruments R^1 and R^2, and shunted with a condenser *c*, of considerable capacity. Between the lower plate of the condenser and the junction of the bridge and earth-wire an additional electro-magnet, *r*, was placed, acting upon the armature lever of the relay R_2, and in the same direction. The effect of this arrangement is, that when the current of one polarity ceases, the condenser *c* immediately discharges through the magnet *r*, which acts upon the armature lever of relay R_2, and retains it in position for a brief time before the current of the opposite polarity arrives, and thus serves to bridge over the interval of no magnetism between the currents of opposite polarity.

It will be seen that the combination of transmitted currents in this method differs materially from any of those used in previous inventions. They are as follows:

1. When the first key is closed and the second open . . . . −1
2. When the second key is closed and first open . . . . −3 or −4
3. When both keys are closed . . . . +3 or +4
4. When both keys are open . . . . . +1

Here we discover another very important practical advantage in the system under consideration, which is due to the fact that the difference or working margin between the strengths of current required to produce signals upon the polarized relay and upon the neutral relay respectively, may be increased to any extent which circumstances render desirable. Within certain limits, the greater this difference the better the practical results, for the reason that the range of adjustment of the neutral relay increases directly in proportion to the margin. The ratio of the respective currents has been gradually increased from 1 to 2 to as high as 1 to 4, with a corresponding improvement in the practical operation of the apparatus.

From what has been said, therefore, it will be seen that before it became possible to produce a quadruplex apparatus capable of being worked at a commercial rate of speed upon long lines, it was essential that its component parts should have arrived at a certain stage of development. When in the early part of 1872, simultaneous transmission in opposite directions was for the first time rendered practicable upon long lines by the combination therewith of the condenser, the first step was accomplished. It now only remained to invent an equally successful method of simultaneous transmission in the same direction, which, as we have seen, was done in 1874. The application of one or more of the existing duplex combinations to the new invention to form a quadruplex apparatus followed as a matter of course.

Thus it is clear that the merit of the invention of 1874 consists in its having furnished us with a new, and what is more important, a practical method of simultaneous transmission in the same direction, applicable to long lines, and not in the mere application thereto of one or more of the known duplex systems, to form a quadruplex, which in itself would no more constitute an invention in the sense contemplated by the patent law than would the application of the duplex principle to the printing or dial instrument used instead of the Morse, with which it was first used.

As its use becomes more and more extended, the quadruplex is constantly undergoing modification and improvement in its minor details, with a view to render its manipulation more simple and easy, and to enable it to be worked direct between the most widely separated points with the utmost speed and certainty. Some of these modifications are very ingenious and interesting, and will probably form the subject of a future article.

ON A SYSTEM OF TELEGRAPHY.

A COURSE OF LECTURES, DELIVERED AT THE SCHOOL OF MILITARY ENGINEERING, CHATHAM.

By W. H. PREECE, Member Inst. C.E., &c.

LECTURE III.—COMMERCIAL TELEGRAPHY—PART II.

[Continued from vol. iii, page 244.]

THE speedy restoration of communication upon busy circuits is a matter of such importance that it is a question for great consideration whether it is not advisable to erect, on important trunk lines, a spare wire for the sole purpose of restoring communication when faults occur upon any of the working circuits. Certainly all important centres should and are connected by a sufficient number of wires to leave a margin for pressure due to possible breaks down which cannot always be prevented even on the best organized systems.

But daily tests also effect a second purpose, and that is, they supply the superintendent with a constant record of the condition of the circuits, so as

Engineering Aug 11th 1882.

A Train Telegraph.

A trial was made recently on the Atlanta and Charlotte Railway, in America, of a new plan for enabling a railway car in motion to communicate by telegraph with the stations on the line. It is the invention of Captain C. W. Williams, U.S.A., and consists of a telegraph line laid along the track but interrupted at frequent intervals, and the ends of the break brought to key blocks mounted upon the sleepers or "cross ties." The key blocks carry two metal rollers, to which the ends of the line are connected, and when these rollers are depressed they interrupt the circuit of the line. When in their normal position the circuit of the line is complete. The bottom of the special car, which is selected as a telegraph office, has a projecting shoe covered with two metal strips or bars which, as the car passes along the line, make contact with the rollers and depress them, thus interrupting the circuit at that point, and thereby throwing the telegraphic apparatus of the car into the circuit at that point. This is effected by having the apparatus connected up between the two strips. These are made of sufficient length to keep the car always in circuit with the line by the rapidly succeeding key blocks and rollers. The current enters the car through one roller and strip, and after passing through the telegraph instrument on board returns to the line through the other strip and roller. The advantages of this system may be considerable in certain American districts, or in case of accident. It enables a station-master to clear the position of a train on the way; or two trains to inform each other of their whereabouts. The establishment of such a system would, however, entail considerable expense in this country owing to difficulties of insulation. In the trial at Atlanta some 200 yards of track were adapted to the apparatus; the key blocks being placed every 40 ft. Messages were received in the car when at rest and in motion, the highest speed tested being 25 miles an hour.

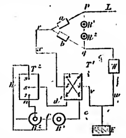
Electrical news July 22 1875

ON QUADRUPLEX TELEGRAPHY.

We are indebted to Professor Zetzsche for a paper on the subject of "Quadruplex Telegraphy." In it Professor Zetzsche quotes, from a work of his published in 1865 ("On Copying Telegraphs, &c."), by way of showing that the possibility of such telegraphing has been for some time in contemplation in Germany, an object both of theoretical inquiry and practical experiments. Of this the Americans seem not to have been aware.

Referring to Dr. Nicholson's method, he remarks that the three different strengths of current employed are in the same relation to each other as in M. Maron's system, only that the latter experimenter employs the current strengths +S, −S, and −3S. M. Maron also uses only one relay, but with *three* permanent magnetic armatures.

"Characteristically new, on the other hand," he proceeds, "is the way in which Prescott and Edison produce the three requisite strengths of current, inasmuch as they give to the line the constant current (Ruhestrom) +S, and use, in telegraphing, −S, +2S, and −2S. Of the key and battery arrangement for this, unfortunately, F. W. Jones gives* no information. The arrangement which I have sketched in the annexed figure meets the conditions perfectly. In the state of rest of both keys, T_1 and T_2, the copper pole of battery B_1 is in metallic connection, through the working contact, 6, and the rest contact, 3, of the double key, T_1, with the key-axis, 2, and through the wire, *x*, with the angle-point, *r*, of the Wheatstone bridge, in whose diagonal, *p q*, the two relays, R_1 and R_2, are inserted; while the end-points, *p* and *q*, of the diagonal, are connected, on the one hand, with the line L, and on the other, through the rheostat, W, and wire, *u*, with the



earth. The zinc pole of this battery, again, is connected, through *f* and *h*, with the rest contact, 9, of the key T_2, with the key-axis, 8, and through the wire, *d*, with the working contact, 1, and the rest contact, 4, the key-axis, 5, and through the wire, *v*, with the earth, E. Both keys are furnished with contact-springs in such a way that the key-lever, immediately after the one spring has left the rest contact, is brought into connection, through the other contact-spring, with the working contact, and *vice versa*. If, now, the lever of the key, T_2, be pressed down, there will be introduced, besides B_1, the battery portion, B_2, through *n*, the rest contact, 7, and the axis, 8. At the other station, therefore, R_2 will answer to the increased positive current, while the tongue of R_1 will still remain in the position of rest. If, on the other hand, T_2 remain at rest, and T_1 goes into the working position, the copper pole of B_1 is connected through *c*, 6, 5, and *v* to earth, E; the zinc pole through *f*, *h*, 9, 8, *d*, 1, 2, *x*, and *r*, to the line L; whereupon, at the other station, both relays, R_1 and R_2, are actuated by the increased negative current, to indicate the signals given by both keys, T_1 and T_2.

Such an arrangement has a not unimportant advantage over the older ones, in that only two relays are necessary for the receiving apparatus. Along with this advantage however, the arrangement has two drawbacks. For, at the transmitting station, there occurs, at each movement of the key, during the suspense, an interruption (though ever so small) of the line, giving reason to fear a rupture of the signals; at the receiving station, on the other hand, when the key, T_2, is held down, and the lever of T_1 moves up and down, the relay, R_1, may not liberate its armature although the current changes its sign. Unfortunately these two defects are of such a kind as (it is to be feared) to forbid the practical employment of this arrangement which is the more regretable, that the advantage of the method might warrant the hope that it constituted a further step towards the successful realisation of quadruple telegraphy. The value of such a mode of connection, however, I regard as consisting, not so much in its making possible the simultaneous sending of four telegrams on one wire, as in the fact that through it a perfect solution of the problem of duplex telegraphing and of transmitting two messages in the same direction at once is afforded; inasmuch as, to each receiving telegraphist is furnished also a key for interruption, and to every transmitting one a receiving apparatus, with which he may be cut off from the station working with him."

19

"Morse," which was less liable to get out of order, and which avoided the troublesome operation of preparing paper chemically, and which has recently been still further improved by supplanting the embossed paper with a pen, which records its character in ink.

This later form of apparatus is in very general use throughout Europe, but it is not the fittest, and it will probably not survive other forms which are developing themselves.

The speed with which an instrument works is usually registered by the *number of words* it can transmit in a *minute*, but owing to the regularity with which messages retain their average number of words, *the number of messages* transmitted *per hour* is now the usual criterion. Messages average 35 words, and words average 4·6 letters. Hence roughly, half the number of messages per hour equal the words per minute. The earlier Morse could not exceed six words per minute, but the rate at which the instrument now works on short circuits is simply the rapidity with which the operator can manipulate his key; 70 messages per hour are frequently obtained by experts, but it is difficult to maintain such a speed. The human machine tires, errors occur. His manipulation loses clearness and legibility. Bain invented the automatic apparatus to replace the human machine by a mechanical contrivance. This secured precision in the formation of the characters, accuracy in the despatch of messages, and speed in the transmission of work. There were, however, defects in Bains' apparatus, and automatic telegraphy was not a success until Sir Charles Wheatstone introduced his beautiful apparatus which is now in such extensive use, and without which it would have been impossible for the Postal Telegraph Department to meet the requirements of the press.

(To be continued.)

The electric telegraph system is still in its infancy, and although its operations are marvellous, yet it is probable that we are at present but imperfectly acquainted with the full extent of its advantages. In this country the telegraph wires are simply used for the transmission of messages, but to Armenia belongs the honour of discovering that they may be adapted as clothes-lines for laundry purposes. The practice of hanging linen to dry on the wires has lately become general in that country, and revealed the hitherto unknown fact that the Armenian peasantry are in the habit occasionally of washing their clothes. Much dismay has, however, been caused by an order that has been issued by the authorities forbidding the continuance of this arrangement. It seems that the wires have on more occasions than one been broken by awkward washerwomen, and Shefket Effendi, an Armenian Semiamore, who has just been appointed director of the telegraph at Erzeroum, has solemnly declared that no more shirts, stockings, or other garments shall be hung on the wires on any pretence whatever.

Professor Cornu, of the *Ecole Polytechnique*, Paris, has put into successful use a new instrument for measuring the velocity of light between two stations, in which an electrical registering apparatus is used, giving, it is believed, more accurate measurements than the well known toothed wheel arrangement of Fizeau. Foucault fixed the velocity of light, by his instrument, at 185,157 miles per second. Professor Cornu, by his new instrument, fixes the velocity of light at 186,660 miles per second, 1,503 miles faster per second than Foucault.

ON THE TELEGRAPHIC PROBLEMS OF DOUBLE SENDING AND QUADRUPLEX TELEGRAPHY.

By C. E. WINTER,
Telegraph Engineer to the Madras Railway.

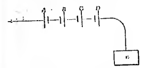
(Continued from page 219.)

There are several ways of accomplishing this; perhaps the best is as follows:—

Let us suppose the full battery to consist of four cells (any multiple of that number would do as well). Let us represent them thus:—

Let this be supposed to give two units of copper current to line.

Now suppose one of them, A, to be reversed by a reversing key, we shall have—



thus A and B neutralize each other, and we shall have one unit of copper current to line.

Next let us suppose A B and C to be reversed by the depression of the other key, then we shall have—

or one unit of zinc current to line.

Lastly, let us suppose both keys depressed, then A, which is reversed by the first key, will be set right again, and we shall have—

or B and C will neutralize A and D, and we shall have no current to line.

The following figure is a conventional mode of

20

DUPLEX ARRANGEMENT, WITH TRANSLATOR, OF M. KOCH, OF CHUR.

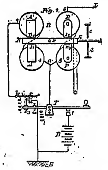


Fig. 2

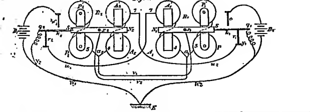
Fig 3



In the first of the above figures (which we borrow from *Dingler's Polytechnisches Journal*) illustrating this system, 1, 2, and 3 represent the working contact, the axis, and the back contact, respectively, of an ordinary Morse key, on which, at its further end, an insulator c is fixed, which, on pressing down the handle, raises the lever $h f$ from the contact i, connected with earth E. The line-battery B is inserted between 1 and E. Of the two corresponding stations, one has the copper pole, the other the zinc pole of the battery to earth, so that the currents of both are in the same direction. The relay R contains two pairs of coils A, A', and P, P'; while A and A' form an ordinary horse-shoe electro-magnet (with unmagnetic core), the cores of the horse-shoe electro-magnet P, P', as in the Hughes type-printer, stand on the poles of a permanent horse-shoe magnet, and are so induced by it, that in P a north pole n_2, and in P' a south pole s_2 is produced. With the aid of an iron piece the magnet can be pushed one way or another so as to adapt the magnet strength to the current strength. Between the four poles of the relay is the magnetic bar N S, the continuation of which, k, plays between the set screws c and d, and on its application to the working contact r closes the local battery. The coil-end 6 is connected with the telegraph line L, the end 7 with the lever h, and the key axis 2 with the point a in which the two coil-ends 4 and 5 unite.

In order that the relay may be inserted suitably to the direction of current, each station is provided with a commutator U (figs. 2 and 3) with 3 and 4 plates. To the four vertical plates are connected the four coil-ends 4, 5, 6, and 7; to the three horizontal plates the lever h, the line L, and a or the key axis 2. The station which has zinc to earth, arranges the stops as in fig. 2, so as to connect 4 and 5 with a and 2, 7 with h, and 6 with L. The station with copper to earth arranges as in fig. 3, connecting 6 and 7 with a and 2, 5 with L, and 4 with h.

When neither key is depressed, and therefore no current passes through the line, the north pole N of the armature, if equally distant from the two cores in A and A', is attracted equally by them; but if unequally distant, it is attracted most strongly by the core nearest to it. The south pole S, on the other hand, is repelled by the south pole s_2 in P', and attracted by the north pole n_2 in P, and therefore the armature takes the position with k on the rest-screw d.

If only one key T, is depressed, and the battery B closed at 1, at the same moment that c raises the lever $h f$ from i, then at the sending station the current goes from 1 to 2 and a, only through the coils P and P', and into the line L; thus in the cores of the electro-magnets P P' the magnetism is neutralised, but the armature is held by the core nearer to it in its position at d. At the receiving station, on the other hand, the current coming from L passes successively through the coils P and P', A and A', and then goes over $h f$ to earth E; thus not only is the magnetism of the cores in P and P' destroyed, but the cores of A and A' are magnetised, a south pole s_1 being developed in A, and a north pole n_1 in A'. Hence the north pole N of the armature is repelled from n_1 and attracted by s_1, and k is brought against the working contact-screw c.

If both keys, lastly, are pressed down at once, the strengthened current goes at both stations only through the coils P and P', and it not only destroys in their cores the magnetism present, but develops in them contrary poles; P thus becomes southly magnetic, and P' northly magnetic. The south pole accordingly moves from P' to P', k becomes applied to c and closes the local battery.

If $h f$ is raised from i somewhat after the instant at which the battery B is closed, the current goes for a time at the sending station also through A and A'; not in the same direction as a current from the other station passes through A and A', but in the opposite; hence in this case the home-relay will not speak, if this is free from a current; if, on the other hand, it is traversed by the current of the other station, the action of this in A A' and the added action of the weak branch of the home-current going through P P' will be easily overcome by the much stronger branch of this current passing through A A', and so the arriving signal be spoiled. If, on the other hand, $h f$ be raised from i somewhat before the key lever closes the working contact, then during this time no way to earth would remain for the current coming by the line from the other station. In this case also, therefore, each movement of the key might spoil the coming signal, and this is as much to be guarded against as a short passage of current through A A' in the previous case. Where, however, it is a case of very small intervals of time, the circumstance that neither the action of the branch current in A A' occurs instantly, nor, on cessation of the current in P P', has the former magnetism again its original strength, may help over the difficulty.

The coils of the electro-magnets A A' should have more windings than the coils of P P', that with earth connection of the line, the action of the weaker arriving current at A A' may not also have to overcome the not quite perfect demagnetisation of the core of P P' produced by it.

In using the arrangement as translator, the continuation k of the armature lever of the duplex relay R is furnished with a further prolongation q insulated from k, and this is opposite the set-screw r as contact-screw. The zinc poles of the two batteries B_1 and B_2 (fig. 4) of the translation station are connected to earth E by the wires w_1 and w_2; their zinc poles applied to the contact screws c_1 and c_2. The continuations q_1 and q_2 also are connected, by thin spirally-wound wires, with the earth. From the ends 7 of the coils A'_1 and A'_2, go wires u_1 and u_2 to r_2 and r_1; from the axes x_1 and x_2 of the armature N_1 S and N_2 S_2 wires v_1 and v_2 to the points of union a_2 and a_1 of the coil ends 5 and 4. To the ends 6, lastly, come, at P'_1 the line L_1, at P'_2 the line L. The armature-lever has, for the same reasons as before, as small a space to play in as possible between the contact-screws c and r.

If now a current comes from L, it passes through P'_2 and P_2, A_2 and A'_2, goes from 7 in the wire u_2 to r_1, q_1, y_1, and in w_2 to earth E; the relay R_2 thus speaks, q_2 removes from r_2 and k_2 is applied simultaneously to c_2; accordingly the current from B_2 now goes from the zinc pole in the wire w_2 to earth E, and from the copper pole over c_2, k_2, x_2, through the wire v_2 to a_1, and from here only through P_1 and P'_1, over 6 into the line L_1, but without the relay R_1 speaking, and interrupting the passage between r_1 and q_1 for the line current coming from L.

Tel Jour Oct 15. 77.

SCHWENDLER'S duplex method is now introduced into the telegraph service of Bavaria, and has been working since the beginning of July, under very variable atmospheric conditions, with great rapidity and regularity, to the satisfaction of the Administration. The great productive power of this method must be sought in the stability of the balance, which renders correcting adjustments almost superfluous. It will apply above all to long lines, as has been proved by several years experience in the Indian service. Switzerland and Wurtemburg purpose making early trials with this method in order to study its more extended application. —*Journal Telegraphique.*

Tel Jour Dec 1, 78

SUBMARINE QUADRUPLEX.—Dr. Alexander Muirhead, together with Mr. G. Kift Winter, the inventor of the closed circuit duplex system in use in India, and Mr. J. A Briggs, have invented improvements in duplex and quadruplex telegraphy, whereby the latter system can be applied to submarine cables. The patent description was communicated from Madras, where Dr. Muirhead recently sojourned while duplexing the Madras to Penang Cable.

SUBMARINE DUPLEX.—In reply to communication to the *Times* by Mr. Herring, Sir James Anderson states the Eastern Telegraph Company are now working Muirhead's duplex system on the Marseilles-Malta section (825 miles) at the rate of 26 words per minute, whereas by simplex they only attain 15 words per minute. The increase of speed on all the sections from Malta to Bombay is at least 70 per cent. With regard to land lines, Sir James says that on the company's line between London and Porthcurnow, a distance of 320 miles, as many as 54 words per minute can be sent as against 25 by simplex.

22

which the capacity is increased to 700 must of necessity give two profits, while the capital has not been increased except by the extra cost of instruments, which in comparison with the cost of construction and maintenance of another wire, it is not necessary to take into account.

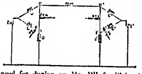
There are at present working successfully in this country five different systems of duplex: 1st and 2nd, the differential and bridge systems of Mr. Stearns; 3rd, the polarized relay system of Mr. Haskins; 4th, the system of Mr. D'Infreville; and 5th, Mr. Gerritt Smith's arrangement, lately described in the *Telegrapher*. The systems of Mr. Stearns have also been described in the *Telegrapher*. No description, however, has appeared of Messrs. Haskins or D'Infreville's inventions. The former arrangement is working very successfully on the North Western Company's lines between Milwaukee and St. Paul. I hope Mr. Haskins will soon give the fraternity a description of it through your columns. No one can do it better.

All the foregoing systems, except the D'Infreville, use condensers for counteracting the effect of the return current. In Mr. D'Infreville's system condensers are not necessary, the current of charge and discharge being rendered harmless by an arrangement of electro-magnets. Messrs. D'Infreville and Haskins also dispense with transmitters, only ordinary keys being used in their arrangements. The D'Infreville requires no instruments (with the exception of rheostats) which cannot de found in every telegraph office,

In the description of Gerritt Smith's duplex arrangement, given in the *Telegrapher* and *Journal of the Telegraph* a few weeks ago, it is stated that in this, as in all other systems of duplex, it makes no difference whether the batteries at each end are placed with similar or dissimilar poles to the line. The writer of the article cannot be acquainted with the D'Infreville system or he would not have written the foregoing. In the D'Infreville system the batteries must oppose each other, and, if I am not mistaken, I think that in Mr. Haskins' system they must *not* oppose, but be placed in same way as in an ordinary Morse circuit.

In both of Mr. Stearns' systems, and I should suppose in Mr. Haskins' also, it is possible to work other lines from the batteries used for the duplex. I understand, however, that this is not generally done. In the D'Infreville system this cannot be done with advantage, and I think the same remark will apply to Mr. Smith's arrangement.

In these days, however, of sulphate of copper batteries, this cannot be considered a very serious objection. In the diagram two stations are shown



arranged for duplex on Mr. D'Infreville's plan The line is of 7,500 ohms resistance.

A A' and B B' are ordinary relays of 200 ohms resistance.

E E' are ordinary Morse keys with the circuit closer removed.

D D' are main batteries, of equal strength, with similar poles to line. The current from each battery passes through receiving relays A A' to the line, only a very small portion of it going through the shunts formed by the rheostats and recording relays. Of course, as the batteries oppose each other, both receiving relays remain open. By depressing key E we close relay A'. The current from battery D is now short circuited through recording relay B and rheostat C, 300. The current from battery D' coming over the line also takes the same route to the ground, and relay A' at once closes. Relay A, however, remains open, owing to the current coming from battery D', meeting with a sufficient quantity of current from battery D (which leaks past the point F) to balance it. This balance is obtained by varying the resistance in the rheostat C, marked 300, so that when key E is closed (the key at the other end being open) the armature of relay A does not move. Relay A' being thus closed, let us see how relay A can be closed from the other end of the line. We close key E' battery D' being thus short circuited, the current, which before went over the line to preserve the balance at relay A is cut off, and the small portion of current which leaked past point F now goes on to point H, and thence through rheostat C, 5,000, and key E, to the ground, and relay A closes. Relay A', which had already been closed, is kept so by the leakage current, which acts the same way as at the other end. It is thus shown that no matter in what position the keys may be, the relays are always ready to respond to the writing from the other end.

The return current is neutralized by the recording relays B B' as follows:—When the line is at rest it is charged with a current of the same polarity from each battery. When the key at either end is closed the current in the line would, in discharging through the receiving relay, make a false signal; at the same instant, however, the recording relay, through which a strong current is passing, sends out an inductive current, which, running in an opposite direction to the current that produced it, meets and effectually kills the discharge current. On raising either key the line is again charged, and this current is again neutralized by the current given out by recording relay on being demagnetized. The strength of these inductive currents can easily be varied to suit any line or condition of line, by using relays of different resistances and size of core. The arrangement shown in the diagram has been working between Toronto and Montreal, on the Dominion Telegraph Company's lines, a distance of nearly 400 miles, for the last year, and is giving good satisfaction. One hundred and forty cups, of ordinary sized gravity battery, are used at each end.

The American electric Society have lately furnished a room in the Western Union building very handsomely, which is open to any of its members. They have quite a library—some of the best books on electricity published in this country—and will soon have many others, among which will be some from societies in Europe. They are preparing their first book, which will contain some line cuts of different late inventions.

23

Institution of Civil Engineers, when the anniversary address was delivered by the President, Dr. Mann. In alluding to the establishment of a carefully planned series of observing stations by the society, the President illustrated at some length the absolute necessity of following out the inductive method of research in meteorology, and supported his argument by a reference to the history of all the leading branches of physical investigation. The President compared the meteorological doctrine of high and low pressure areas of the atmosphere, and of the movement of currents of the air under the influence of barometric gradient, to the Newtonian doctrine of gravitation in astronomical physics, to the Daltonian hypothesis of atomic proportions in chemistry, to the dynamic theory of the tides, and to Avogadro's law of the uniformity of the atomic constitution of gases under like conditions of pressure and temperature. He maintained that the perfection and practical application of this law must be worked out by organised and carefully-thought-out plans of observation, such as were now used by the society, and also under circumstances of higher opportunity and greater facility by the meteorological office of the Government. The President incidentally remarked that he believed the recent researches into the vertical circulation of the water of the ocean under the influence of the different specific gravities of its distant parts was virtually tending to the establishment of the same great influence as being the moving spring of the physical dynamics of both the ocean and the atmosphere. In allusion to the recent establishment of the permanent lightning-rod committee by the society, he gave a very interesting account of a visit he had recently made to Professor Melsens, of Brussels, and described the experiments upon which the professor is engaged in investigating the molecular changes brought about in conducting bodies by the passage through them of powerful discharges of high tension electricity. He also gave an elaborate account of the admirable system of defence against lightning which has been adopted at the Hotel de Ville of Brussels. Some curious and notable instances of the molecular effects of lightning discharge were exhibited during the delivery of the latter portion of the address. The report of the Council having been read, the proceedings concluded with the election of Mr. H. S. Eaton, M.A., as President for the ensuing year, and the appointment of the usual officers.

THE TELEGRAPH ELECTRICAL SOCIETY, MELBOURNE.

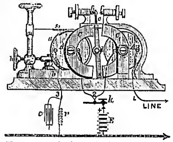
We have been favoured with a copy of the transactions of the Telegraph Electrical Society of Melbourne for the quarter ending 31st July, 1875, along with the report for the year ending the same date. The society has just completed the first year of its existence, and now comprises 49 town members and 79 country members. Their meetings are held in the chief telegraph office at Melbourne, so that ready access may be had, when required, to large battery power and apparatus, which could not be well moved were the meetings held elsewhere. The proposal to make the society a public one, and admit strangers as members, has been negatived, and the rights of membership are restricted to the *employés* of the Postal Telegraph Service. Several valuable papers upon various subjects have been read; and the present number of the transactions includes, amongst others, a valuable note, by Mr. H. J. Aubin, upon automatic translator for closed circuits. Altogether, the society seems to be in as flourishing a condition as can well be expected.

HASKINS'S DUPLEX TELEGRAPH.

(From the *Telegrapher*.)

Since the first patent was taken out in this country for duplex telegraphs by Moses G. Farmer, in 1858, nearly forty other patents, including reissues have up to this time been granted in the United States for inventions of this kind, mostly within the past five years. We have from time to time published in the *Telegrapher* diagrams and descriptions of several different methods of duplex telegraphy, including most if not all of those which have been employed in actual telegraphic service in this country, with the exception of the one which forms the subject of the present article.

The apparatus we are about to describe was invented in the early part of 1871 by Mr. C. H. Haskins, General Superintendent of the lines of the North Western Telegraph Company at Milwaukee, Wis. It is one of the simplest in principle, as well as one of the most effective in operation, of the numerous inventions of the kind now before the public. The novelty of the invention may be said to consist principally in the peculiar manner in which the receiving relay is constructed and operated, and we will, therefore, give a somewhat detailed description of this part of the apparatus before attempting to explain the general principle of operation.



The accompanying illustration is an end view of the relay, the connections and other parts of the apparatus being shown on a small scale and in outline, for convenience of explanation. The relay consists of two spools or helices, A A_1, which are placed parallel to each other, and connected together at the point 2, so as to form a continuous circuit from 1 to 3, precisely in the same manner that the helices of an ordinary relay are arranged. Instead, however, of connecting the two cores

THE TELEGRAPHIC JOURNAL.

Vol. I.—No. 11.

DUPLEX TELEGRAPHY.

By W. H. PREECE, Memb. Inst. C.E. and Soc. T.E.

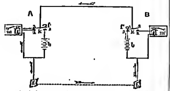
Duplex telegraphy, which has lain dormant in England for nearly seventeen years, has recently received great attention from all telegraphists, owing to its successful introduction in America by Mr. Stearns. This method of working consists in telegraphing in opposite directions upon one wire at the same time. It implies that while A is working to B, B can also work to A upon the same wire.

Before explaining how this apparently impossible operation can be performed, I will first show how A usually works to B, by means of an ordinary Morse recording-instrument.

A possesses a battery (*b*) whose number of cells depends upon the distance which separates A and B: a key (*k*) which on being depressed (as shown at B) by the pressure of the fingers at *f* brings the points 1 and 2 in contact, causing the current to flow from the battery (*b*), and which in its normal position (as shown at A) remains with the points 3 and 4 in contact, thereby permitting any current arriving from B to flow through the Morse apparatus or receiver (*m*).

B possesses the same apparatus as A. They are connected up, as shown in the diagram (Fig. 1), the

Fig. 1.



circuit being completed by the earth. When A works to B he depresses the key (*k*), sending a current to B, which, passing through the receiver (*m*), records its mark, and for every current so sent a mark is made. Now when B works to A precisely the same thing occurs—every depression of the key at B occasions a mark to be recorded upon the receiver at A, through the passage of a current from B to A. It is evident that if the batteries at the two places be similar in every respect, and the insulation of the wire be perfect, the currents from each station will be exactly equal in strength. The currents from A to B may be in the same or in an opposite direction to those from B to A. It matters not—the effect upon the recorder is just the same. I have shown them in the diagrams to flow in the opposite direction, and therefore, for the present, we will so consider them. We will also assume, for the present, that the current received at either station is exactly equal to that going out of it.

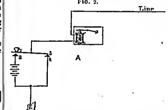
Now what happens when these two stations try and work to each other at the same time? We have a current from A flowing to B in one direction, and we have a current from B flowing to A in the opposite direction: and since these currents are equal, if they tend to flow at the same time, the effect must be *nil*; they, in fact, destroy each other; no current can be formed,—hence with such apparatus no marks can be registered at either station. But what if we can avail ourselves of this destruction of the current to register marks? That is, if we let one instrument be such that it registers when the current is *formed*, and also when the current is *destroyed*. If we can do that duplex telegraphy is possible; A can work to B while B works to A.

This problem was first solved by Dr. Gintl, an Austrian telegraph director, in 1853. Modifications of his solution have been made in Germany by Siemens, Frischen, and others; in England by the writer, and Mr. Eden of Edinburgh; and in America by Mr. Stearns. There are three methods adopted: first, that of *equation*; second, that of *difference*; third, that of *leakage*.

1. *Equation*, which was the method originally invented and applied by Dr. Gintl.

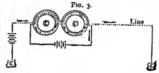
The connections are so arranged, as shown in Fig. 2, that the receiver at each station is always

Fig. 2.



in circuit, so that the currents, whether they are sent by A or received from B, pass through it; but it is so constructed that when A alone is working no effect is made on its own receiver by the outgoing current. How is this done? The electro-magnet, E', Fig. 3, which is shown here in plan, is wound

Fig. 3.



with two wires, of exactly equal dimensions and resistance, either of which operates equally upon the iron core when traversed by the same or an equal current. The character of the magnetic polarity imparted to an iron core by a current depends upon the direction of the current. If a current in one direction produces a *north* pole at at the uper end, a current in the reverse direction produces a *south* pole at the same end. If these currents acted simultaneously, the result would be no polarity at all, for the tendency to induce the one

26

On one side is advertised "Post Office, Money Order Office, Savings Bank, Postal Telegraph," and on the other "Pickles, Cattle Medicine, Perfumery." The postmaster controls and supervises all the sub-offices under his charge.

The head offices are placed in direct communication with each other, and with the chief centres, such as Manchester and Birmingham, which again in their turn are connected with the chief telegraph station in London, known as T S, so that messages are sent from place to place by the most direct routes, and every office is provided as much as possible with alternate circuits or double outlets in cases of accident or pressure.

The system before the transfer of the telegraphs to the State was mainly directed to place London in communication with the Provinces, but the Post Office has placed all towns that have business relations in direct communication with each other, and has diverted as much as possible the circulation of messages through London. It has done all in its power to prevent the unnecessary repetition of messages, and to reduce the number of transmissions to the fewest possible, for every transmission means increased cost in working and extra liability of error.

All head offices as a rule are worked by Morse circuits; some few still remain worked by needle circuits, but gradually, as the business increases, the needles are being supplanted by the Morse and the Morse by the sounder. Where several offices remain on one circuit, the needle is retained, but intermediate working induces delay, and as soon as the business admits of it, direct wires, fitted with Morse instruments, are supplied. Head offices are almost invariably worked by trained telegraphists, either in the employment of the postmaster or directly in the service of the Crown. All the large transmitting centres are worked entirely by a trained and experienced staff, under the direct control of the postmaster of the town in which it is placed.

It may be taken as a rule that, when the messages are very few, A B C instruments are used. When the number of stations on a circuit exceeds four, or when the number of messages exceeds twenty per day, then single needles are fixed. As the business increases the single needles are replaced with Morses. When the number of messages exceeds fifty per day it is time to consider the necessity of a direct wire. One such wire can transmit without delay 150 messages per day. If the messages approach 200 a day, another wire is wanted. If the distance between the stations and the amount of business warrants the expense, then Wheatstone's automatic is fixed, and this can readily transmit from 400 to 600 messages per day.

Recently duplex telegraphy, which enables messages to be sent simultaneously in opposite directions on the same wire, has been introduced. It simply duplicates the capacity of all *direct* wires, and it has placed in the hands of the Postal Department, a most valuable and useful auxiliary apparatus. Indeed without it, and with the recent stoppage of all works, it would have been difficult to have transacted all the work of the Department during the very busy autumn which has just passed, without inconvenience or delay. It is applicable to all kinds of instruments.

It may be said generally that the teaching of experience is showing that the instrument of the future for ordinary commercial work is the "sounder."

(To be continued.)

A NEW SYSTEM OF ELECTRIC TELEGRAPHY.

By PAUL LA COUR,
Sub-Director at the Meteorological Institution of Copenhagen.

(Presented to the Royal Danish Academy of Sciences at the Meeting of February 12, 1875, by Mr. Holten.)

IN the Electric Telegraph, up to the present time, but two simple signals have been employed, and these have been formed either by currents in opposite directions, or by the prolongation, to a greater or less extent, of the duration of the current. The system, which I devised on the 10th May last, enables, however, a large number of simple signals to be made with a single connecting wire.

When a vibrating body, at each of its vibrations, is made to close and open an electric circuit, the pulsations of the current will, of course, be isochronous with the vibrations of the sonorous body; and when such currents are, by means of electro-magnets, made to act upon a second sonorous body vibrating in unison with the first, the second body will vibrate, whilst another similar body giving a different sound will remain silent.

The first experiment was successfully made on the 5th June, 1874, but it was feared that the vibrations might cease to be perceptible after traversing a long distance. I therefore made an experiment upon a telegraph line, 320 kilometres in length (from Copenhagen to Fredericia and back), and even with a rather weak current, the pulsations were easily perceptible. This experiment was made during the night of the 14-15 November in the same year.

To produce the intermittent currents and receive them at the farther end, the sonorous bodies employed were tuning-forks. The apparatus is constructed in the following manner:—

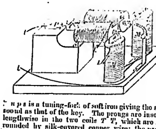
The key or instrument, which produces the intermittent currents in the line, is shown in the following figure:—

S S is a tuning-fork fixed by the shank in such a way that at each oscillation one of the prongs touches the contact *c* during a portion of the oscillation. The contact *c* can be adjusted by the screw *k*, and together with its support, is insulated from the tuning-fork by the insulating piece *J*.

When the shank of the tuning-fork is connected to one of the poles of a voltaic battery whose other pole is to earth, and when the contact piece is connected with the telegraph line and thence to earth, a blow given to one of the prongs of the fork will cause an intermittent current to be sent into the line, the pulsation of the current being in unison with those of the fork.

It follows that, by keeping the fork in vibration, the same result will be obtained, whenever the circuit is closed at any given point. It always follows that, by employing a contact upon the inside of the fork with a special battery for the same, the line can be charged with a succession of currents in opposite directions.

The receiving apparatus is shown in the next figure.



n p s is a tuning-fork of soft iron giving the same sound as that of the key. The prongs are inserted lengthwise in the two coils *T T*, which are surrounded by silk-covered copper wire; the prongs are so arranged as to vibrate freely within the centres of the coils. The intermittent current, on arriving at the station, passes through these two coils, and thence into the wire of an electro-magnet *M M*, which is arranged so that its poles are placed in front of the opposed poles produced in the fork. It is evident that the current, in magnetising the electro-magnet and the fork, produces an attraction which will open the prongs of the latter, but directly the current, and consequently the attraction, ceases to operate, the prongs will return to their position of equilibrium, and so on. If then the pulsations of the current are in unison with those of the fork, the vibrations of the latter will soon attain a sufficient extent for one of the prongs *n* to touch the contact piece *D*, closing the circuit *l l* of a local battery, and thereby manifesting the arrival of the current in the usual way, either directly or by means of a relay.

I cannot as yet, I admit, state the time required to produce in the fork of the receiving apparatus vibrations of a certain extent; it is a function of various factors; but experiment shows that the time which elapses before the local circuit is closed is so small a fraction of a second as to be hardly perceptible, even when the current is very weak. In the hope that this system will play an important part in electric telegraphy, I beg to here point out its principal advantage.

The intermittent current acts upon that tuning-fork only which is in unison with the fork of the key. If then any number of different keys are arranged and the same number of receivers to correspond, an equal number of simple signals can be produced, each of which requires but a single movement. If each of these signals corresponds to a letter, figure, or other sign, messages may be sent more quickly than by present methods, and the receivers can be made to act upon a printing apparatus without any difficulty.

The same peculiarity will admit of the employment of these signals where several stations are connected together by a single cable. A signal can be sent between any two of the stations without the others being aware of it. The system might also become applicable in various other circumstances, for example: to call, give warning, announce the occurrence of an accident, fire, torpedoes, &c., in a word in all cases where it is desired to transmit signals only to certain points.

Another important property of the system is that *several signals can be produced* SIMULTANEOUSLY *upon the same wire.* For when several keys are acted upon at the same time, the current thus produced, with simultaneous intermissions of different duration, will only act upon the receivers corresponding to the vibrating keys, if only the forks have been selected in such a way as to avoid simple harmonies between them. Thus, for example: by employing a system of ten tuning forks, ten simple signals can be produced, then $\frac{10 \times 9}{1 \times 2} = 45$ signals when combined two and two, without the latter requiring more time than the simple signals. The question of the limit to the number of forks which can be vibrating at the same time is one that can only be determined by experiment.

The same property makes it possible to transmit several messages to various stations, employing but one wire. For example; station A is connected by a wire with station B, whence the wire is continued to station C. Station A can use two different systems of keys, one for station B and the other for station C. The receivers at the two stations must, of course, correspond with the keys. The same property also enables the system to be employed for pantelegraphs of a more reliable and quicker form than those made by Bain, Caselli, and others. Up to the present time only one style has been used in such telegraphs, and this style has to pass over the whole surface of the telegram to produce a copy of it; in the new system, however, as many styles as may be desired can be placed side by side in the form of a comb, which will then pass over the surface of the message in one direction only. By this method also, there is the advantage that an exactly equal speed is not required in the two instruments, for the only inconvenience which would result from a difference of speed between the original and the copy would be a slight contraction or extension in width of the whole message.

Lastly, the receivers have the valuable peculiarity of *letting ordinary electric currents pass through them without any indication of their presence,* at least, unless the currents are of very considerable intensity, so that atmospheric and terrestrial currents would not, as a rule, interfere with the working of telegraphs arranged upon this new system.

27

The quadruplex system, by which two messages are sent simultaneously from both ends of a line was successfully worked on the Madras Railway line between Madras and Salem a few weeks ago. — S.M. Oct. 75

28

ON THE TELEGRAPHIC PROBLEMS OF DOUBLE SENDING AND QUADRUPLEX TELEGRAPHY.*

By G. K. WINTER.

THE practical success which has attended the revival of duplex telegraphy has doubtless led many besides myself to inquire whether the difficulties in the way of the simultaneous transmission of two messages in the same direction, over the same line, were altogether insurmountable. A very little thought over the matter will show that the difficulties to be encountered in solving this problem are altogether of a different nature from those attending the question of duplex working, and, further, it is evident that if once these difficulties were overcome, the problem of quadruplex telegraphy would be solved by applying to our apparatus similar arrangements to those by which duplex telegraphy has already been rendered practicable.

It is obvious that, to send two messages at the same time, in the same direction, on the same wire, between two stations, two keys are required; and it is also obvious that with two keys, each having independently two positions, there are four combinations, which of course should each produce a different effect upon the receiving instruments at the distant end. Thus suppose we have two keys, which we will call A and B respectively, we shall have—

1st	combination.	Both keys at rest.
2nd	"	A depressed and B at rest.
3rd	"	B depressed and A at rest.
4th	"	Both keys depressed.

* Communicated by the Author.

There are two different ways of attacking the problem, namely—

1. To devise such an arrangement of the keys that each of the four combinations shall produce a different electrical effect on the line, and then to endeavour so to arrange the receiving instruments that these different electrical effects shall be rightly interpreted by them.

2. To endeavour so to arrange the receiving instruments that, with some four variations in the electrical state of the line, four combinations, analogous to those of the keys we have noticed above, may be produced; and then to devise some arrangement of the keys by which the desired electrical states of the line may be produced by their action.

I have only seen two systems described in any of the works on electricity or telegraphy that I have read. One is given by Blavier and the other by Sabine. In each of these it would appear that the inventors had set to work according to the first method, for in each the method of joining up the keys is practically the same, and intended to produce currents as follows:—

1. Both keys at rest. No current.
2. A depressed and B at rest. One unit of current.
3. B depressed and A at rest. Two units of current.
4. Both keys depressed. Three units of current.

All the currents being in the same direction.

This is the most obvious arrangement of the keys, and it will be seen, from the following descriptions of the methods, that in each of them the inventors have been successful in rightly interpreting the different signals sent; thus, supposing the local instruments at the receiving station to be Morse instruments, we find that—

1. When no current arrives, both Morses are at rest.
2. When one unit of current arrives, Morse A is acted upon and Morse B is at rest.
3. When two units of current arrive, Morse B is acted on, Morse A is at rest.
4. When three units of current arrive, both Morses are acted on.

So that at first sight the problem would appear to have been solved in each case: on examining the matter further, however, we shall find that false signals would be made during the changes from one combination to another, which, apart from another drawback we shall notice, would suffice to render the methods useless.

The method given by Blavier is as follows:—R, R', R" (Fig. 1) are three relays joined up one after another between the line and the earth at the receiving station.

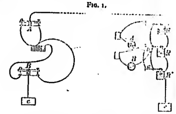
(over)

Of these R is the most sensitive, and will work with one unit of current.

R' is rendered less sensitive by means of an opposing spring: it will not work with one unit of current, but it will with two.

R" is rendered still less sensitive by means of a stronger opposing spring: it will not work with less than three units of current.

FIG. 1.

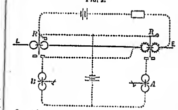


It will be seen that the Morse A is joined up in such a way that, so long as the relay R' is at rest, it will work whenever the tongue of relay R is acted upon by the current. So long, therefore, as the key A only is worked, and consequently only one unit of current sent into the line, the Morse A will indicate the signals given by the key A. When the key B is depressed it is evident that two units of current are sent into the line; consequently the current is strong enough to work both the relays R and R'. The relay R' in working completes the circuit of Morse B, and at the same time breaks the circuit of Morse A; thus, so long as only the key B is worked, the Morse B will indicate the signals given by the key B. Now suppose we depress both keys, there will be three units of current, and consequently the relay R" will be worked as well as the others. It will be seen that when relay R" is worked, the break in the circuit of Morse A which is caused by the working of relay R' is made good, and thus both Morses will be worked. So far all well, but now let the key B be raised; the current will be reduced to one unit, and consequently both the relays R' and R" will be drawn back. Of course the circuit of Morse B will be broken, but so also will for an instant that of Morse A, for it is evident that the tongue of relay R" will have broken contact with *c* before the tongue of relay R' can have made contact with *b*, and thus recompleted the circuit of Morse A. Thus at the change there will be a sudden interruption of the working of Morse A, not answering to any signal given by its key, and a confusion of signals must arise.

Added to this, however, the difficulty of keeping the three relays at proper states of sensitiveness would be almost insurmountable. The difficulty of the interruptions of the circuit in the intervals between the positions of rest and depression of the keys could be overcome by known methods.

The system given by Sabine was invented by Stark, of Vienna, in 1855. The method of connecting the keys was somewhat different from that shown above, but the result was exactly the same, so we will only concern ourselves with the receiving apparatus: this is represented in Fig. 2.

FIG. 2.



In this arrangement only two relays, of different degrees of sensitiveness, are employed. Relay R is the most sensitive, and will work with one unit of current; relay R' is less sensitive, and will work with two units of current, but not with one. When relay R' works, however, it not only completes the circuit of the Morse B, but also that of another circuit through an extra coil of the relay R, in such a direction as to oppose the action of the currents coming from the line, and thus to render it less sensitive, and only to be worked by three units of current in the line circuit.

According to this plan, whenever the key B is worked both relays will work, for it is not until the relay R' has made its contact that the sensitiveness of relay R will be reduced; consequently at every depression of the key B we shall have a momentary kick on the Morse A, not in accordance with any signal given by its key, and thus confusion of signals must result. Again, although we have only two relays to adjust as to sensitiveness, yet one of these has two states of sensitiveness, one of which, namely, that caused by the opposing action of the local current, would be even more troublesome than the adjustment of the third relay by means of a spring. Neither of these methods can therefore be said to offer any hope of practical success.

Having now examined the principles and learnt the defects of the old systems, I will endeavour to explain, as clearly as possible, the principle of the system by which I have achieved a practical success, and the line of thought which led to its discovery.

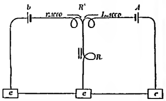
ON THE TELEGRAPHIC PROBLEMS OF DOUBLE SENDING AND QUADRUPLEX TELEGRAPHY.*

By G. K. WINTER.

(Concluded from page 210.)

IN Fig. 3 let L be the line with a resistance say of 1000 units, and let *r* be an artificial resistance of the same amount. Let *b* be a local battery, and A a battery at the distant station, of equal strengths, and sending their currents in the directions indicated by the

FIG. 3.

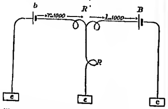


arrows; *e*, *e*, *e*, are earth plates. R' is a relay wound differentially, and R is another relay, not wound differentially, but connected between the middle point of R' and earth, as shown in the figure.

It is evident that the two currents will neutralise each other's effect on the relay R', but that they will both flow through R in the same direction. R' will evidently not work, but R will.

Again, let Fig. 4 represent the same arrangement, except that the direction of the battery B is reversed, as shown by the arrows. Then the currents will flow in the same direction through the two coils of the differential relay R', which

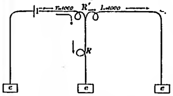
FIG. 4.



will consequently work, whereas no current will flow through R, as the potential of the circuit at the centre of the differential relay will be zero, the batteries being equal in power, and the resistance equal on each side of this point. Thus in this case the relay R' will work, but not the relay R.

Next, let us have no battery applied at the sending station, but the line joined to earth, as shown in Fig. 5.

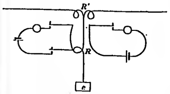
FIG. 5.



It is now evident that both relays will work, for a large portion of the current from *b* will flow through R to earth. Thus with three variations of current coming from the sending station we can produce three of our four combinations. It remains to be seen how we can produce the fourth.

Let us suppose the differential relay R' to have two tongues, and let the connections be made as shown in Fig. 6. Further, let this relay be polarised, and let both its tongues be worked by a current in the direction shown by the arrows in Fig. 5.

FIG. 6.



We must also suppose that when in a state of rest—that is, when no current is passing through the relays—the tongues will be in the positions shown in Fig. 6.

Things being thus arranged, let a current from B be sent, as show in Fig. 7.

We shall then have a current running through one coil of R' not only in a direction opposed to that from *b*, but also of double the strength, and consequently the resultant magnetic effect of the currents on this relay will be to give it a polarity which will be opposed to its working; thus not only is the tongue *t'* allowed to fall away from its contact, but is held in that position, while the tongue *t* is also forced away from its contact-point, against which it leans

TÉLÉGRAPHES HARMONIQUES

POUR LES TRANSMISSIONS SIMULTANÉES

De M. Elisha GRAY

(*Suite*)

Le second système de télégraphe harmonique de M. Elisha Gray, que nous avons mentionné à la fin de notre précédent article, a pour objet d'utiliser un fil conducteur ordinaire interrompu, desservant un certain nombre de bureaux intermédiaires, de manière à en faire un fil continu susceptible de

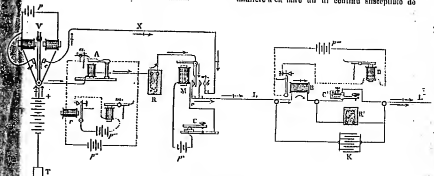

Figure théorique d'une ligne pour transmissions simultanées.

transmettre les correspondances échangées entre les stations extrêmes par deux systèmes télégraphiques différents, fonctionnant simultanément. C'est en quelque sorte un *Duplex* d'une nouvelle disposition qui a l'avantage de pouvoir être appliqué sur toutes les lignes déjà en service, et sans changer leur organisation.

Le problème était assez difficile à résoudre sur les longues lignes, et ce n'est qu'après de nombreux essais qu'il put être résolu d'une manière tout à fait satisfaisante. Sans entrer dans les détails de tous ces essais que M. Elisha Gray donne dans son mémoire, lu à la Société des ingénieurs télégraphiques de Londres dans sa séance du 12 décembre 1877, nous allons indiquer le système tel qu'il a été expérimenté en Amérique, entre Chicago et Dubuque, et tel qu'il figure à l'Exposition de 1878.

Le fil allant de Chicago à Dubuque s'étendait sur une longueur de 180 milles et desservait dix-sept bureaux intermédiaires, fonctionnant avec des appareils Morse. Or, ces bureaux ont pu correspondre entre eux comme à l'ordinaire sans troubler en quoi que ce soit le travail effectué entre Chicago et Dubuque au moyen du double système.

La disposition du système est indiquée dans la figure ci-dessus qui représente la combinaison des appareils pour un seul des postes extrêmes. L'autre poste est disposé exactement de la même manière, et rien n'est changé à la disposition des postes intermédiaires, sauf qu'on y a ajouté un rhéostat et un condensateur. L'ensemble des appareils de ces postes est exactement représenté dans la partie de la figure ci-dessus que l'on distingue à droite.

Chacune des stations extrêmes comporte donc deux séries d'appareils que nous avons disposés en deux groupes, de manière à ce que l'on puisse aisément distinguer ceux qui appartiennent aux transmissions harmoniques de ceux qui appartiennent aux transmissions Morse. Ces derniers sont à droite, les premiers à gauche. Les appareils pour les transmissions harmoniques sont les suivants : 1° une clef Morse du système Gray C, servant d'organe manipulateur; 2° un relais transmetteur M, agissant sur deux circuits issus de la pile de ligne P, l'un passant par le récepteur harmonique A et un rhéostat R, l'autre traversant le vibrateur V; ces deux circuits sont équilibrés et correspondent tous deux à la ligne L; 3° un récepteur harmonique A, dit *analyseur*, qui réagit sur un parleur ou sur un relais local *r*, et par suite sur un Morse *m*; 4° un vibrateur V analogue à celui que nous avons décrit dans notre précédent article, et qui doit être réglé pour vibrer synchroniquement avec l'analyseur; 5° un rhéostat R pour équilibrer la résistance des deux circuits dérivés au A et au V.

Les appareils pour les transmissions Morse so-

147,487. G. D'Infreville, New York, and W. N. Armstrong. *Duplex telegraph.* Dated April 25, 1873. —No additional local or split batteries used. Two main batteries opposed, and battery at sending station localised, for preserving equilibrium. 1. The method of duplex telegraphing, substantially as described, by localising or short circuiting the main battery at the sending station, thereby preserving the magnetic equilibrium in the signalling instrument of that station, and allowing the battery of the receiving station to exert its full force in recording or indicating signals. 2. In combination with a normally closed telegraphic line having main batteries, one at each terminal, connected to the line in opposition to each other, open circuit single contact keys, and branch circuits connected to the relay magnets at a suitable point, the closing of the said keys short-circuiting or localising the battery of the sending station through the proper proportion of the coils of the relay. 3. In combination with a relay magnet having its layers exposed for connection to key, and for approximate adjustment, as described, the shunt circuit and rheostat. 4. In combination with the normally closed line, having branch circuits and open circuit single contact keys, and opposed batteries, as described, the battery reversers and closed circuit keys. 5. The combination, at an intermediate or way station, with the main line of a duplex telegraph, of the open circuit key and branch circuit connected to the relay between the terminals, the depressing of the key closing independent circuits for both terminal batteries, giving signals to both sides of the way station in single transmission, or forming a duplex line with one terminal.

32

Western Union and Quadruple Transmission.

To the Editor of the Telegrapher.

Will you permit me, through the columns of The Telegrapher, to reply to a statement in regard to the "most erroneously" assumed advantages to accrue to the public by the use of an alleged new discovery referred to in the New York *Tribune* of the 9th instant—said new invention being called by the electricians of the Western Union Telegraph Company "The Quadruple Telegraph." By the use of which each wire now in daily use is not, and cannot, as stated, be made practically four; further, that by its use the traffic of the company cannot, as stated, be economically increased without the erection of any more wires. It being a well known fact, both here and in Europe, that specially large wires had to be erected for the "Stearns Duplex." This, taking the cost of construction or reconstruction into consideration, leaves practically the line working on the "old Morse status," at least until reconstruction is paid for.

Now, with regard to the so-called quadruple system said to be in use between New York and Boston; it is also a well known fact that it is being worked necessarily on a large line wire, for, by an apparently curious "paradoxical law," the speed of duplex, as also the speed of quadruple transmission over even a large line wire, is "reduced with mathematical precision," and this reduction of speed progresses rapidly for quintuple transmission, and so onwards until finally speed will entirely cease altogether. This fact is also well known to telegraph scientists—in a succinct way it means that if we erect, say a number six line wire for quadruple transmission, there will be (when the state of the weather admits of its being worked) practically a gain of only one wire. But, on the other hand, if it be attempted to work quadruple transmission on an old Morse line wire the gain will be practically *nil.*

This "new discovery" by the way, for some twenty-five years known to all telegraph scientists, which fact must have inadvertently been overlooked by my scientific friend, Mr. George B. Prescott—being described in the works of that eminent electrician, General Sabine, and others in 1854-5-9. Nevertheless, to Mr. Prescott is due the credit of its first introduction in this country. Now, for the sake of argument, admitting the statement referred to to be correct, let us see what would be the gain to the company according to Mr. Prescott's book, p. 149. The average rate upon Morse lines does not exceed seventeen words per minute, and this is a fair average—add seventeen words more for quadruple transmission, leaving the same still subject to all of the old Morse difficulties, such as climatic changes, liability to interpretation by feel, taste, or by sound by any Morse operator, and may be so appropriated; and, in addition, the same is subject to the inevitable fourfold complication of the Morse apparatus when adapted to quadruple transmission, and over sixteen compensations in order to meet, among other difficulties, that of ever varying climatic changes constantly taking place throughout this vast extent of continent.

What the people of this country require is a reliable, cheap system of telegraphy, whereby they may feel sure at all times of obtaining telegrams during any state of the weather, and that is to be found in the one upon which the eyes of the whole scientific world is now centred—namely, the (my) American (electro-chemical) automatic telegraphic system of the first order, which is capable of transmitting and receiving two hundred words and upwards per minute; one automatic line wire above referred to being practically equal to twenty Morse line wires. Within the past four years my rapid American (electro-chemical) automatic telegraph has repeatedly been pressed into the service of the opposition company during such seasons of stormy weather when the electro-magnetic telegraph came to a stand still. I hope you will excuse my trespass on your space when I tell you that in the year 1846, on this very important question of telegraphy, I stood before a committee in the British Parliament cheek-by-jowl with Alexander Bain.

ing with the signal instruments of the present day.

(To be Continued.)

Notes.

Bryant and May's safety matches are highly electrical, and if they be rubbed against glass or ebonite they readily ignite, especially if these electrics be dry and warm. How far their ready ignition on amorphous phosphorus is due to chemism, and how far to electricity, remains to be proved.

Nature says that a French clerical journal maintains that the tolling of the church bell is of much greater efficacy than the use of lightning-rods in warding off the effects of a thunderstorm, and advises the faithful to resort to the former means in preference to the latter.

The Anglo-American Telegraph Company have just given notice that telegrams can now be sent to Mexico, but that the lines there do not work very regularly.

Owing to delay in getting the material ready to put down, the Western Union Telegraph Company have decided not to attempt to lay the pneumatic tubes and underground wires between their general office and the branch offices on Broad and Pearl-streets until early in the spring. The work could not be conducted to advantage during the severe winter weather now soon to be expected. No part of the plans regarding the experiments contemplated, however, have been changed.

In transmitting the President's message from Washington to New York on Thursday, Dec. 7th, the Western Union Company used eighteen wires, and the time occupied was 30½ minutes. The message contained about 13,000 words, and copies were dropped at Baltimore and Philadelphia.

We learn from America that the Direct United States Cable Company state that the recent breaking of their cable in the Atlantic cannot be accounted for in any other way than that the break was caused by some vessel, but whether from accident or design is not at present known, and they decline to express an opinion on the subject. They declare, however, that the cable on examination recently was in perfect order, and that considerable force must have been used to disarrange it. The company offered a reward of £1,000 for the discovery of the vessel which broke the cable. The second break has been successfully repaired.

The first annual meeting of the American Electrical Society was held in Chicago on Wednesday, Nov. 17th, and was very largely attended, many members from various sections of the country being present. The president of the society, Gen. Anson Stager, presided.

Mr. Thomas Slater writes that the new prism electro-magnet of M. Sommati, described at p. 277 of our number of Dec. 1, 1875, was previously invented and patented by him two years ago.

It has recently been recommended by M. Saint Edme that lightning conductors should be constructed entirely of iron, protected by a coating of electro-deposited nickel.

The Direct United States cable, broken on the 10th ult., was repaired on the 10th inst., the *Faraday* having made a successful expedition.

The repairs to the first break were completed in a remarkably short time, especially if the season of the year be considered. The *Faraday* left the Thames, arrived at Newfoundland, completed the repairs, and was back again within a month.

It would seem likely that the present expedition will be equally expeditious. However, it is to be hoped that the direct cable will be left alone for the remainder of the winter, for it would be most desirable that the result of cheap American telegraphy should be known.

The Anglo-American Company's receipts for Saturday the 8th inst., at 3s. per word, amounted to £2,040, and for Sunday to £630; against an actual average in January last year, at 4s. per word, of £1,785.

During a heavy gale off Madeira the line end of the Lisbon-Madeira section of cable was broken. It was repaired in a few days, the fault evidently being easily accessible. The *Hawk* was despatched at once, and will now not be required, as the repairs were completed shortly after her departure.

The Suez-Aden section of the Eastern Company's cable is still broken down. The *Chiltern* has arrived at Aden, but the repairs are still incomplete.

D'INFREVILLE'S DUPLEX TELEGRAPH.

By HUGH NEILSON.

(*The Telegrapher.*)

Though the duplex invention has lately been rather thrown in the shade by its "big brother," the quadruplex, it still remains, and, for a year or two at least, is likely to remain the most reliable means of working off business between large cities, especially when such cities are more than 250 miles apart. If an ordinary Morse circuit between two large cities can carry 350 messages a day, on which the company make a profit, an arrangement by

ON THE TELEGRAPHIC PROBLEMS OF DOUBLE SENDING AND QUADRUPLEX TELEGRAPHY.

By G. K. WINTER,
Telegraph Engineer to the Madras Railway.

(Continued from page 236.)

—

PART II.

A second method of double sending which I have successfully worked, follows, almost as a matter of course, from the system previously described.

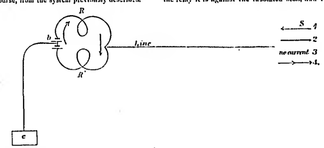

FIG. 12.

Let b be a battery, R and R^1 two relays, and let them be joined up with earth, and line in the manner shown on fig. 12. Let S be the distant station, and let the four combinations of the keys at that station produce the currents represented by the arrows, &c., opposite 1, 2, 3, 4, respectively. The current represented by the arrow opposite 1 will aid the local current through R^1, but will neutralise that in R. Again, the current represented by 2 will aid the local current in R, but will neutralise that in R^1. No current, represented by 3, will simply allow the local current to flow through both relays, and the double current represented by 4, will not only neutralise the local current in R^1, but will cause a current in it in the opposite direction to that in which the local current is flowing. Let both relays be polarised and so connected as to be worked by the local current. If now R^1 be a relay with two tongues, the position of rest of one of them being against the insulated stud, and that of the other against the central point; while the position of rest of the tongue of the relay R is against the insulated stud, and the tongues joined up as shown by fig. 13, we shall have exactly an analagous action in the relays to that described in the first part of this paper. This system possesses certain advantages over the system previously described; it is simple in theory, requires less battery power, and necessitates neither a differentially wound relay nor a bridge arrangement.

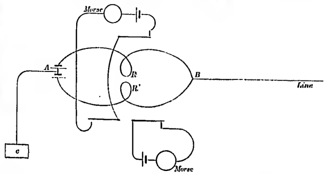

FIG. 13.

N.B.—The tongues are shown in their positions of rest.

This system works exceedingly well, and of course the same arrangement of keys will suit either method. In order to duplex this system, we join the two branches of the bridge to the points A and B, and put a resistance coil between A and earth, adding condensers to this coil if necessary. Since the first part of this paper left, I have worked the quadruplex arrangements described without any difficulty.

It is very desirable that the currents should be properly balanced in the relays R and R^1, and it is also evident that the resistances of the two branches in which they are placed should be equal. In order to secure those conditions I make the following arrangements:—

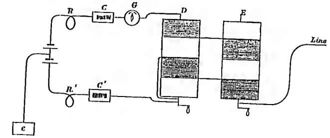

FIG. 14.

R and R^1 are the two relays as before, C and C^1 are two resistance coils for coarse adjustment, G a galvanometer, and D and E are two barrels of a rheostat by which the finer adjustments are made; the barrel D is of ebonite or other insulating material, and the barrel E is of brass or other conductor; by turning the barrels equal increments or decrements are effected in the resistances of the two branches.

We will now analyse the changes in the positions of the tongues of the relays which are caused by the action of the keys.

Fig. 15 shows the position of the tongues and the direction of the currents when both keys are at rest. It is seen that both the tongues $t\ t^1$ of relay R^1 are open, while the tongue t^{11} of relay R is closed. Both local circuits are therefore open.

Now suppose that key to be pressed which causes a current ——> in the line.

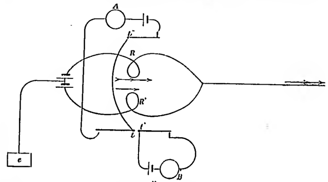

FIG. 15.

The current in R is simply reduced from three units to two units, so that the tongus t^{11} continues closed. The current R^1 is neutralised, so that the tongue t falls to its position of rest against the contact points, and thus completes the circuit of·

37

If he does anything to offend me in the least. Tell him anything, so you stop him from coming. I am going to see a nice young lady in this town, and dear knows what she will do if she finds I have acquaintances like that man."

Mack told him it would be impossible to stop him, that he had gone out now to try and steal a meal somewhere. "You had better receive him kindly," he concluded, "and don't aggravate him by treating him coolly, as he might abuse you, and he don't stop at anything when he is mad." McGrew answered very weakly, "*I have the necessary courage, but I haven't the strength and muscular ability to cope with him.* I will have some of my friends here with me when he comes, to protect me." The next night he called us up, and asked if Bosmus started for his place. Mack said, "Yes; keep a look out for him, he will be there soon." McGrew replied, "I have three men with revolvers and a shot gun in the office waiting for him. I have been to all the stores and hotels in town, and told them not to trust this man on my account, as I would not be responsible for any debts of his contracting." This was too much for Mack and the boys, they almost expired with laughter. Poor McGrew! He found out a few days afterwards when he was in town how cruelly he had been sold. He ceased to trouble us with "I am McGrew—brother of Bob's," and we were once more tranquil and happy.

[From *The Telegraphic Journal*.] Sept 1874

Duplex and Quadruple Telegraphy.

By Arthur R. Granville.

Without question, the Americans are maintaining their ground for ingenuity and enterprise in the electrical inventions. Although the practicability of duplex telegraphy was known as a scientific curiosity quite twenty years ago, it was far in advance of its age, and could not be put to any use by reason of certain difficulties—insuperable, according to the then known laws of electricity—so that the invention lay fallow for that period. A further reason for the invention not being followed up may be found in the fact that the traffic of those days was easily met, and telegraph engineers were not goaded on to investigate the difficulties attending the introduction of a system which, by enabling lines to perform twice their previous amount of work, has virtually doubled the efficiency of the wires in use.

To an American, Mr. Stearns, belongs every credit for dispersing these difficulties by a happy use of the condenser. Though not the inventor of the system—the honor of the invention belonging to Dr. Gintl, of Vienna, and W. H. Preece, of Southampton, Messrs. Siemens, Halske and Frischen, of Berlin—yet to him belongs the highest praise for having resuscitated an old laboratory experiment; for having nursed and trained it from infancy to maturity; and for introducing it to the practical world as a valuable system, requiring but slight additions to the instruments in use amongst telegraphers to render it ready for immediate practice. And so successful has the working of the "duplex" proved, that in a little over two years it has established itself as a great and most profitable system, and may be regarded as indisputably one of the most important turning points in the history of telegraphy and electrical science. It is reckoned equal in importance to the discovery of Steinheil, who demonstrated that return wires could be dispensed with by the use of earth plates. In resultant effects the "duplex" is strikingly similar to Steinheil's discovery, since both have doubled the resources of telegraphy—the former *directly*, by actually doubling the working capacity of wires; the latter by halving the lengths of lines, inasmuch as return wires were proved to be no longer needed.

The benefits arising from the "duplex" system bid fair to be multiplied still further by the joint labors of two Americans, Messrs. George B. Prescott and Thomas A. Edison, who announce the perfecting of what they designate "the quadruple system." This system is described as a "new process of multiple transmission, by which two messages can be sent simultaneously in the same direction over the same wire, and either message can be dropped at any way station on the circuit." The "duplex" system can also be applied to this "multiple" system, so that *four* messages may be despatched together over the same wire in the same direction. The recommendations in favor of the "quadruple" are that, like its predecessor, the old Morse key can be used, and the only expense attending its introduction is the purchase of additional parts of machinery; there is no sweeping away of old appliances and substitution of new ones. The Western Union Telegraph Company, of which Mr. Prescott is Electrician, is about to try this system—in fact, put it into practice on all their lines—so that we shall shortly learn with what success the system is capable of being worked. Of this we may be certain, that should fail

Duplex, Quadruplex and Fast Telegraphy.

The following extracts from a communication of Mr. D. H. Craig, in a recent number of *The Graphic*, will be found of interest. It will be noticed that he intimates that the "Quadruplex," even if successful, is not available to the Western Union Telegraph Company:

In President Orton's recent annual address to the shareholders of the Western Union Telegraph Company much stress is laid upon the "Duplex" and high hopes placed upon the "Quadruplex" systems of telegraphing. These systems are doubtless improvements upon the Morse system in the number of words which can be transmitted over a single wire in a given time in fair weather, but the claim of the inventors and their friends that the capacity of the wires of the Western Union Company can be doubled by the "Duplex" or quadrupled by the "Quadruplex" system may answer very well to bolster up the stock of the "monster" company amongst the speculators in Broad street and the curbstone philosophers in New street, but there is not a practical operator who values truth in the employ of the company who will say that 1,500 words per hour can be averaged, one hour and one day with another, by "Duplex," nor that 2,500 words can be averaged by the "Quadruplex." If the same operators had independent wires, the first four would prefer to send 2,000 words (instead of 1,500 by "Duplex"), and the eight operators would prefer to send 4,000 words instead of 2,500 by "Quadruplex"), one hour and one day with another. A moment's consideration, therefore, will show the utter fallacy of the claim of the President and Electrician of the Western Union Company, either that the capacity of their wires can be doubled or that the business of telegraphing can be at all cheapened by the "Duplex" or quadrupled or "cheapened" by the "Quadruplex." So far are these statements from being correct that it is quite within the truth to say (and the practical telegraphers of the Western Union Company will confirm my statement) that it would cost the company at least twenty per cent. more—labor and wires included—to do their business by the "Duplex" than it would by the Morse system, and it would cost at least twenty-five to thirty per cent. more to do the business by the "Quadruplex" than it would by the "Morse." As I have a large and direct interest through the Automatic Telegraph Company (who own all the so-called inventions of Edison in the too much commended "Quadruplex" system), my judgment is not likely to err on the wrong side. I may also say that no one having authority has ever proposed to give the Western Union Company permission to use the "Quadruplex" system; and it is difficult to imagine what purpose Mr. Orton had in his extravagant allusions to it, unless it was to lend support to some of his "lame-duck" friends in Broad and New streets.

The well affected enthusiasm of the managers of the Western Union Company in favor of "Duplex" and "Quadruplex" telegraphy is by many supposed to be for the purpose of hiding their ignorance and brazen effrontery in 1869–70 in denouncing my "Automatic" or "Fast" telegraphy. At that time the President and Electrician of the Western Union Company insisted that there was no system of telegraphy equal to Morse (and this in the face of the fact that "Duplex" telegraphy was then thoroughly established upon the Franklin Boston line), and that my Automatic system was utterly valueless, because, as they said, it could not be worked at a faster speed than about sixty or seventy words per minute in a circuit of 250 miles, whilst the fact is that over 1,000 words per minute have been and can at any moment be transmitted by that identical Automatic system over 300 miles of wire. These gentlemen are too proud, or too conceited, or both, to acknowledge their error, and they have been raising a furious dust ever since, first about one trumpery humbug or another, like "Duplex," "Wheatstone's Automatic," and now about "Quadruplex" telegraphy, and all the time, in place and out of place, through thousands of addresses, reports and "official journals," and through their legions of subservient tools all over the country, a steady stream of misrepresentation has been carried on against my system of Automatic telegraphy. The effect has been thus far, coupled with the ridiculous mismanagement of the Automatic Telegraph Company, to deter capital from taking up the "Fast" or "Automatic" system, and Mr. Orton complacently points to the fact that the Automatic Company has done nothing since 1870–71, as evidence that his original statements were true, and that the "Fast" system is of no account in comparison with his second-hand pet "Duplex."

THE TELEGRAPHIC JOURNAL.

Vol. I.—No. 16.

A DANGER FOR OUR IRON SHIPS.

Not long since were lost two of the best steamships ever floated, the *Atlantic* and the *City of Washington*; and not only is their loss a serious public calamity, but it places before the scientist a point requiring his unremitting attention. Of the cause of the loss of one of these vessels, it is so far certain that the navigating officer was misled by a deviation from the true line of the ship's compass needle. Placing the usual implicit trust in the magnetic needle, the captain steered his vessel not to her destination, but to destruction. The disturbing cause, affecting the truth of the compass, is said to be the load of iron, steel, and tin in the ship's hold; and how many ships put to sea, built of iron, or with cargoes of iron, that are open to the same cause of error, accident, or destruction.

But it should be known that this source of danger is not unprovided for; that, on the contrary, the greatest care is taken, in the case of an iron ship, to detect and compensate for this error. For determining the deviation due to the ferruginous material employed in their construction, iron vessels are "swung" in different directions; and the variation is noted between the indications of a standard compass placed in as nearly neutral situation as can be found—that is, at a point where the local attractions are evenly balanced—and the indications of the binnacle or ship's compass. A table is constructed upon the data afforded by these variations, and by this table is regulated the course of the ship when lunar or solar observations cannot be taken. But great as the care that may be taken in the calculation of the table—and the care taken by our naval architects and builders is exceedingly great—such care may in a moment be rendered valueless, for the vessel may acquire a new magnetic polarity very different from that with which she left the dock.

We know that magnets are of two kinds, permanent and induced. The needle of the compass is a permanent magnet. It is also known to scientists that a shell or iron bar laid in the magnetic meridian—north and south—will become temporarily a magnet; and that if struck or smartly jarred whilst in this position, that the bar will acquire a certain magnetic polarity quite sufficient to affect the ordinary compass needle. What of this? Why, an iron ship is but a big bar of iron, which, if running north and south, may be rendered permanently magnetic by the percussion of the waves against its sides, or even by the sharp strokes of the working of its own engines in a storm. Instances far too numerous are on record of the truth of this theory. The *Tiber* and the *Snowdon* both lost, or had their magnetic polarity reversed by the sharp blow of a minor collision. The *Aphrodita*, with a known deviation of her compass needle of 21° 30', ran against a pier, and the deviation was lessened by four degrees, showing that in an iron vessel the time when most is required from the compass—perhaps in the dark, when a vessel has struck—that instrument is useless. As to iron cargoes, it has been known that an iron ventilating shaft, placed near the standard compass, has quite misled the navigator. Many methods have been proposed in reference to the remedy of this defect. The latest, perhaps, is that of M. Glösener, who suggests "the placing of the standard compass out upon the bowsprit, at a distance previously determined to be without the sphere of attraction of the iron in the vessel. By this means, instead of the attracting substances being grouped around the instrument, perhaps unequally, they necessarily are all upon one side of the compass, and symmetrically placed in regard to it. The latter is, of course, so fixed, that the lubbers point and the foot of the needle pivot are in a line parallel to the longitudinal axis of the ship. To reflect a portion of the card, an inclined mirror is arranged above it, in which the indication is read from the deck by means of a glass." But some of our iron ships are constructed without bowsprits, even if the method were a reliable one, so that the subject still calls for the earnest attention of our scientific men. For the study of the subject means the saving of valuable property, nay, the saving of innumerable invaluable lives.

DUPLEX TELEGRAPHY.

By W. H. Preece, Memb. Inst. C.E. and Sec. T.E.

(Continued from page 247).

3. *Leakage.*—It now remains for me to explain the third method of duplex working, which has been adopted practically, and which is less known than any of the other methods because it has not been published before this, although it was worked experimentally, in the year 1856, between Southampton and Cowes. Our busy practical engineers have, as a rule, so much work to do, that they have no time to write and publish accounts of all the trials and experiments upon novel plans and new apparatus which they make, especially when their results are not entirely successful. Consequently

38 Tel. Jour. June 1874

It is stated that in consequence of the great success of the duplex system of telegraphing, by which messages are transmitted through a wire in opposite directions at the same time, and by which a considerable reduction has been made in the manual labour of working, the Post Office contemplates the immediate reduction of existing charges in a ratio of about 50 per cent, and are making inquiries with the view of carrying the object into effect. The difficulty of obtaining increased office space for additional instruments and additional clerical assistance, certain to be required, seems the only obstacle at present to be considered.—*Court Journal.*

T.J. June 1874

ll find the Queensland Government officials at the or place ready to receive it and connect their land s.

n official memorandum, dated July 27, from the tern Telegraph Company (Limited) states: "This company's direct cable to Lisbon is repaired, thus restoring submarine telegraphic communication with Portugal, Gibraltar, Malta, Egypt, India and the far East."

The Eastern Telegraph Company have notified that their Vigo-Lisbon cable, which was interrupted by the steamship Chimborazo last week off the river Tagus, is now repaired, so that the whole of the company's lines are in perfect working order.

The Western and Brazilian Telegraph Company (Limited) have received intimation that the land lines connecting Rio Grande do Sul with Montevideo will be open for traffic about the 30th inst. Through telegraphic communication will be thus effected between Europe, the River Plate and the west coast of South America. The anticipated delay to through messages for Montevideo, Chili, etc., occasioned by the loss of the steamship Gomos with the Rio Grande do Sul and Chuy cable will thus be obviated.

A new cable between Shetland and Orkney has been successfully laid by the steamer Caroline.

A news report from Kingston, Jamaica, of the 10th inst., states that the submarine telegraph cable between Cayenne and Demerara will not be completed before October. The cable steamship Hooper will return to London for an additional supply of cable to duplicate the line between Demerara and Jamaica.

The Telegraph in Japan.

In a brief account of the progress of the telegraph in Japan, printed in The Telegrapher of May 30th last, it was stated that Mr. Thomas J. Larkin was the superintendent of telegraphs in that country. This was not exactly correct, as his actual position is that of assistant superintendent of telegraphs (of which class of officials there are five), with headquarters at Kobe. The position of superintendent-in-chief of Government telegraphs in Japan has been conferred upon Mr. E. Gilbert, of Glasgow, Scotland, telegraph engineer to the North British Railway Company. Mr. Gilbert, who is a practical telegrapher, is also known as the inventor of a system of electrical communication in trains, and other electrical inventions.

The Government telegraph lines of Japan extend or are being extended from Tokei to the north of the island of Niphon, and will shortly be connected by a cable with Hakodadi, in the island of Yesso.

It was also erroneously stated in the paragraph referred to that the galvanized iron wire used was made in Japan, which is not the fact, it being imported.

Before the present telegraph staff was engaged for the Japanese lines (in 1871), Mr. Gilbert, a nephew of the gentleman who has now been appointed Superintendent in-chief, was employed by the Government, and built the first telegraph in that country that connecting Yokohama with Tokei, and Kobe with Osaka.

The Duplex System on Long Submarine Telegraph Cables.

In The Telegrapher of July 18th was reprinted from *The Telegraphic Journal* the substance of a letter from Mr. C. V. De Sauty, claiming to have succeeded, after fourteen months of experiment, in solving successfully the problem of applying the duplex system to the working of long submarine telegraph cables. In the number of *The Telegraphic Journal* for August 1st, Mr. H. Smith, of the Eastern Telegraph Company, under date of Malta, July 10th, contests the impression conveyed by Mr. De Sauty's letter of priority in successfully applying the duplex to such cables. He says:

"Mr. De Sauty is to be congratulated on his success after so long a period as fourteen months of experiment. Permit me, however, to point out that Mr. De Sauty's is not the first solution of the problem of submarine 'duplex' telegraphy, as applied to long cables, as would seem to be claimed by his letter.

On my arrival at this station in June, of last year, I found Mr. De Sauty here experimenting on the matter. The instruments used at both ends were Thomson's 'recorders,' and Mr. De Sauty found, on charging and discharging the line, that a sudden jerk of the syphon took place at the same end, which he called the 'kick.' All his attempts to neutralise this having failed, on the 6th of July he returned to Gibraltar, expressing his fear that this difficulty would prove fatal to the success of the system.

After Mr. De Sauty's departure I selected one of the Company's Alexandria cables on which to experiment, as, having duplicate cables, the traffic would be less

A New Duplex Telegraph.

Mr. E. C. Cracknell, at a recent meeting of the Royal Society of New South Wales, read a paper on the "Duplex Telegraphic Instrument." His remarks were listened to with great interest. After sketching the origin and progress of duplex telegraphy, from its first trial by Dr. Gintl, the Director General of Telegraphs in Austria, on a line from Vienna to Prague, in 1853; and briefly describing the devices of Frischen, Siemens, Halske, Stearns and others, he said:

"The arrangement before you this evening is perhaps the most simple duplex working apparatus yet devised. The two instruments are the ordinary Morse recorders, with relays, in every day use on the lines in this colony. The relays are wound with one continuous wire, and the only additions are the two vertical water columns for producing the necessary artificial resistance for dividing the currents, the actual line resistance being equal to 150 miles of wire. With this plan only one battery is employed for the line circuit, which is continuous, that is, in one direction, and the adjustment requires very little attention. It must not be understood that two distinct currents of electricity pass in opposite directions through one line of wire at the same time; but the problem has been solved by increasing the amount of current on the main circuit when signals are sent simultaneously. Although duplex telegraphy may now be considered beyond a doubt as to its practicability, we are not likely to remain satisfied with its success for any lengthened period. Mr. Meyer's ingenious invention of the multiplex telegraph, exhibited in the late Vienna Exhibition, bids fair to eclipse all the telegraph instruments now in use for rapidity of signalling through one wire. This instrument has already been tried between Paris and Lyons, with four transmitters on one line, and 100 to 120 messages of average length are sent through per hour."

Award of the Great American Medal of Honour for the Invention of the Duplex Telegraph.—The *Telegrapher* says: "We recently had the pleasure of inspecting the Great Medal of Honour awarded by the American Institute to Mr. J. B. Stearns, the inventor of the Duplex Telegraph. The medal is made of gold, and is beautifully executed. On the obverse, or face of the medal, are representations of the following objects in relief: The Goddess of Liberty, holding a laurel crown in her right hand, and a staff, surmounted by a liberty cap, in her left; the United States Coat of Arms, a spinning wheel, ship under sail, sheaf of wheat, shuttle, horn of plenty, plough, and the Caduceus or Mercury's rod, the symbol of good counsel, peace, and power. The rod, representing power; the serpents, wisdom; and the two wings, diligence and activity. The reverse of the medal is surrounded by a wreath of oak and laurel leaves, enclosing the following inscription: The Great Medal of Honour, awarded to J. B. Stearns for Duplex Telegraph, 1872. The honour conferred by this award, so justly bestowed upon Mr. Stearns by the Great American Institute, which occupies so pre-eminently high a position in the metropolis of the Western World, is greatly enhanced by the fact, that only one Great Medal of Honour is awarded by the American Institute during any one year, and none unless for an invention of paramount importance." Mr. Stearns, to whom America is indebted for her duplex system, is now in Europe, where we hope his great services to telegraphy will be as fully and unequivocally recognised as they have been in his native land.

Tel Journal Oct 73

Scientific American, Vol. xxix., No. 13.

The Multiplex Telegraph.—On page 64 of our current volume, we called attention to an article in a contemporary, describing a French invention by which four operators can, it is asserted, each work a telegraphic communication over a single wire in one direction simultaneously; and not only this, but four others can operate at the same time in the other direction. A correspondent, J. T., writes to inform us (*The Scientific American*), that the honour of this invention belongs to the United States, and that the original and only inventor of the system by which more than two telegraphic instruments can be worked at the same time over one wire is Mr. Merritt Gally, of Rochester, N.Y., the inventor of the "Universal" printing machine. Mr. Gally's telegraph improvement has been patented in the United States and in some European countries. Our correspondent states as follows:—"By the use of Mr. Gally's invention a large number of operators at different stations along a single wire can be simultaneously employed sending different messages in either or both directions without conflict, each accomplishing as much or more work than would be possible

39

Quadruplex telegraphy has been successfully introduced in America by Messrs. Prescott and Edison, and a large supply of apparatus is being manufactured by the Western Union Telegraph Company. Tel Journal Jan 1875

Quadruplex telegraphy has very recently been accomplished on the Madras Railway Telegraph. The system which Mr. G. K. Winter, the telegraph engineer, invented in March last proved perfectly successful on 80 miles of line, and its extension to lines of greater length is simply a question of additional condensers and battery power. The principle of sending two messages simultaneously in the same direction, on which this quadruple system depends, was successfully worked between Salem and Madras on April 16th last, but unfortunately other duties prevented Mr. Winter carrying out the duplexing of this principle until very recently. His exertions have

far him to do by the use of the Morse key. Mr. Gally has adapted his system to each and every kind of receiver or register. The operator can receive his letter in print or by sound, or both simultaneously; or by the embossing, marking, or the electro-chemical recorder; and his instruments are so simple and accurate in their manipulation that it seems impossible that a mistake could occur in their operations. No time whatever is wasted in adjusting the instruments. They are always in readiness, and the first stroke of the operator sends the first letter of his message. Each touch of the key-board represents a letter or other signal complete. The operator may be sending a message to a distant station, be receiving another from an intermediate or more distant station, and through a third part of his instrument be in active communication with every office on the line, receiving or sending calls or explanations; while on the same wire numerous other operators, all along the line, may be similarly employed. By using the electro-chemical recorder, on Mr. Gally's system, at least sixty operators may be simultaneously employed upon a single wire sending messages to any destination along the line; thus entirely doing away with the necessity of previously preparing the messages in punched slips of paper, as is done for the automatic machine." *The Scientific American* hopes soon to publish full particulars and illustrations of this last addition to and improvement in telegraphic apparatus, the capabilities of which multiply with astounding rapidity.

Lecture Experiments in Electricity.—An extract from a series of papers, entitled, "The Magic Lantern as a Means of Demonstration," by Professor H. Morton, Ph.D.—If a piece of thick platinum or tin wire is bent into a hoop circling the interior of one of the glass tanks above mentioned, and the tank itself is filled with a strong solution of bichloride of tin, then, on inserting another wire at the centre of the solution and connecting with a series of two or three Grove's elements, so as to make the centre wire the negative and the hoop the positive pole, a beautiful growth of metallic crystals will shoot out from the centre, and spread over the entire surface of the field. A similar experiment may, of course, be performed with a vertical tank, but the unsupported weight of the metallic blades then soon breaks them down. In this arrangement, however, they are supported perfectly, resting, in fact, on the bottom of the tank, as the solution should not be more than an eighth of an inch deep. If a small compass-needle be mounted on a pointed support, like an inverted tack or drawing pin, its motions are, of course, vastly amplified in the huge image projected on the screen, and may thus be utilised in a number of ways which are too evident to need mention and too numerous to admit of it. If, moreover, a piece of covered copper wire is bent into a flat rectangle and placed beside the needle, with its ends, of course, in binding screws or mercury cups, it will form a galvanometer quite delicate enough for all ordinary use. It will indeed show the induced current developed by introducing a magnet into and withdrawing it from a helix. This, of course, opens a wide field of illustration. A more complete apparatus for use as a lantern galvanometer has been described and used by Professor A. M. Mayer, of the Stevens Institute of Technology, with great success, but as it involves several modifications in the constructive detail of the instrument, we must refer the reader to the Professor's original description. (See *American Journal of Science*, 1872, vol. iii., p. 474; *Journal of the Franklin Institute*, 1872, vol. lxiii., p. 421; and "The Earth a Great Magnet," Chatfield and Co.) Another arrangement, superior to this for many purposes, and not requiring a vertical lantern, has since been devised by Professor Mayer, and will be found described in *American Journal of Science and Arts*, 1873, vol. v., p. 270.

City and Commercial Notes.

Messrs. Grant Brothers, as bankers and agents of the River Plate and Brazil Telegraph Company, are now offering for subscription £91,000 share capital of this company, in 4550 shares of £20 each, to be issued at par, being the balance of £391,000, the capital required for the completion and working of the whole of the land and submarine cables undertaken by the company. By the statutes of the company, the authorised share capital amounts to £600,000, but advantageous arrangements have been entered into by which the total requisite expenditure will be limited to the amount mentioned above, and, of this, £300,000 has already been subscribed. An exclusive privilege has been granted by the Imperial Government of Brazil for a period of forty years, by the terms of which, power is reserved to the Government to purchase the cables at any period after the expiration of ten years, upon the advantageous terms of paying for the same on the basis of the amount of the earnings of the five previous years; the cable reverting to the Government at the expiration of the terms of the concession; and a reserve fund of 10 per cent of the earnings will be created with a view of providing for the repayment of that portion of the capital represented by the cables. Messrs. Siemens Brothers have already manufactured upwards of 700 miles of the cables, leaving only about 430 miles to be completed. The specifications of the cables have been prepared by Sir William Thomson, F.R.S., and Professor Fleeming Jenkin, F.R.S. The Montevidean Government have granted a concession authorising the construction and working of a network of land lines throughout Montevideo. The construction of the land lines has been entrusted to Messrs. Lamas and Co. The calls on the £20 shares now offered will be payable as follows—viz.: £1 on application, £4 on allotment, and £5 on the 1st of December, January, and February next, interest at the rate of 6 per cent being allowed up to the 15th April next, by which time it is anticipated that the whole of the cables will be duly laid, and cable communication established from the states of the River Plate to Rio de Janeiro, Bahia, Pernambuco, and Para, and dividend will then accrue. It is calculated that the amount of British capital alone invested in River Plate and Brazilian securities and enterprises is between 50 and 100 millions sterling. It is evident that a more rapid means of communication is demanded; when the entire system of telegraph to Europe is complete, communication will be reduced from over forty days to a few hours.

The Eastern Telegraph Company's traffic receipts for the month of September, 1873, amounted to £33,162, and to £29,303 in the corresponding period of 1872.

The Eastern Extension, &c., Telegraph Company's traffic receipts for the month of September, 1873, amounted to £19,128.

The Eastern Extension, &c., Telegraph Company have declared an interim dividend for the quarter ending the 30th June, at the rate of 6 per cent per annum, or 3s. per share, free of income-tax, payable this day.

A memorandum from the Secretary of the Globe Telegraph and Trust Company, Limited, says:—"I am instructed to state that interim dividends of 1½ per cent, or 3s. per share, upon the fully paid preference and ordinary shares of this company for the quarter ending 18th October current, and on the preference and ordinary shares not fully paid, at the rate of 6 per cent per annum on the amounts paid up from the respective dates of the payments, to the same date, will be paid on the 18th inst. The transfer books will be closed from the 15th to the 19th inst."

THE OPERATOR,
THE ORGAN OF THE AMERICAN AND CANADIAN TELEGRAPH OPERATORS AND JOURNAL OF SCIENTIFIC TELEGRAPHY.

The Publishers, in announcing the Fourth Volume of THE OPERATOR, which commences with the number for Sept. 1, 1873, desire to return thanks for the liberal support which it has hitherto received, which it is expected and believed will be continued during the ensuing year.

All the popular and valuable features of the paper will be retained, and it will continue as heretofore to labor for the best interests of the Telegraphic Fraternity, and the advancement of Electrical Science and the Telegraphic Art.

As heretofore, no labor, time or expense, warranted by the patronage received, will be spared to improve its character and add to its interest, and to sustain its reputation as the only first-class Electrical and Telegraphic Journal upon the American Continent.

On Quadruplex Telegraphy.

As furnished by George B. Prescott, Electrician W. U. T. Co.

The simultaneous transmission of two telegraphic communications in opposite directions upon the same wire, now known the name of duplex telegraphy, dates back to the year 1853. The first to conceive of its possibility as well as the first to carry the conception into practical effect, was Dr. Wilhelm Gintl, Director of State Telegraphs in Vienna, Austria. He describes his method in a paper read by him before the Vienna Academy of Sciences on the 9th of June, 1853, and in July of the same year it was put in practical operation between Prague and Vienna.

In March of the following year Carl Frischen, a telegraphic engineer of Hanover, Germany, improved upon Gintl's plan, by making use of a branch current from the main battery for compensating the effect of the outgoing current upon the home relay, instead of a local current employed by Gintl. This is unquestionably the most important improvement which has been made in duplex telegraphy from the time of its original invention by Gintl down to the time of the addition of the condenser by Stearns, in 1872.

Frischen used a different relay having helices composed of two equal parts and opposing wires, and an artificial or rheostat equal in resistance to the main line, substantially as they are used at this day. His first practical experiment was made between Hanover and Gotling on the 26th of May, 1855.

The labors of Frischen, and of Siemens and Halske, of Berlin, who during the same year, independently but subsequently worked out a method almost precisely similar to Frischen's, brought the system of simultaneous transmission in opposite directions to a state of perfection which answered a very good purpose upon the comparatively short lines, and at the slow rate of transmission in vogue at that day.

The success of these ingenious inventions gave an entirely new direction to the minds of the host of enterprising electricians on the continent of Europe, and during the following year, 1855, the problem of simultaneous transmission in the same direction which naturally suggested itself as the next step in the progress of invention, was solved with more or less success by the independent labors of Dr. J. B. Stark, of Vienna, Dr. Werner Siemens, Dr. August, Kramer and A. Bernstein, of Berlin, and Dr. J. Bosscha, Jr., of Leyden; each of these inventors having published a full account of his method in the latter part of 1855 and the early part of 1856. At least two of them, Stark and Bosscha, clearly saw that the successful solution of the difficult problem of simultaneous transmission in the same direction included, as a necessary consequence, the solution of the problem of quadruplex transmission also; for a knowledge of the invention of Gintl, as perfected by Frischen, was all that was needed to show that it was equally applicable either to a single or double telegraph in one direction. In the first published description of his method, dated at Vienna, October 31, 1855, Stark concludes as follows:

"With the method of double transmission in the same direction we may also combine that of counter transmission (gegensprechen), and hence arises the possibility of simultaneously exchanging four messages upon one wire between two stations which will, however, hardly find any application in practice."*

This is unquestionably the earliest published suggestion of what is now known as the quadruplex system.

Dr. Bosscha, in a description of his system read before the Royal Academy of Sciences of Holland, on the 27th of October, 1854, and published in their transactions, Vol. IV, p. 101, not only makes the same suggestion, but sets forth in detail a method of accomplishing the result. Having described his method of double transmission in the same direction, he says: "Now, if we wind each of the receiving relays with two wires, and divide the current at the sending station, according to the plan of Siemens and Halske (Frischen), through the two coils of the home relay in opposite directions, then it becomes practicable for both stations to transmit at the same moment, without their own relays being affected by their own transmitted currents, and it is possible to send four signals simultaneously through one wire. This solves the problem in its largest generality."

Thus Stark and Bosscha, as early as 1855, both recognized the indisputable fact that the production of a successful method of quadruplex transmission depended solely upon the successful solution of the problem of double transmission in the same direction. If this could be accomplished, it becomes a mere matter of mechanical detail to combine with it Frischen's or any other system of counter transmission.

It has been stated that methods of double transmission in the same direction were worked out independently, but almost coincidently, by a number of inventors during the year 1855. The ingenious and active German electricians, recognizing that the accomplishment of this result was the key to simultaneous quadruplex transmission, had diligently labored at the problem. Let us now consider the result of their labors.

In any system of simultaneous double transmission in the same direction two keys are required at the sending station, and at least four different electrical conditions of the line must be provided for, one for each of the four following cases:

1. When the first key is closed and the second key open.
2. When the second key is closed and the first key open.
3. When both keys are closed.
4. When both keys are open.

The methods of Stark, Siemens and Bernstein (No. 1), though varying in detail, were arranged upon one general principle, the four electrical conditions of the line being as follows:

1. A positive current having a strength of 1.
2. A positive current having a strength of 2.
3. A positive current having a strength of 3.
4. No current.

The methods of Bernstein (No. 2), Bosscha and Kramer, and at a later date those of Schreder (1860), and Maron (1862), were arranged upon another and better principle, as follows:

1. A positive current having a strength of 1.
2. A negative current having a strength of 1.
3. A positive (or negative) current having a strength of 2.
4. No current.

There are two serious difficulties, leaving minor ones out of consideration, which are inherent in every system of simultaneous double transmission in the same direction. In the first place, when either key is passing from its front to its rear contact, it causes a momentary interruption of the signal which is at the same time being transmitted by the other key.

Neither Stark nor Siemens suggested any means of overcoming this difficulty. Bosscha and Kramer made use of a device originally invented by Gintl, viz., that of keeping the battery constantly in the main circuit, but shunted by the key, so that when the latter was depressed the short circuit was broken and the current flowed to line, but when raised the battery was again short circuited. This plan effectually disposed of the difficulty in question, but was injurious in its effect upon the batteries. Bernstein, however, hit upon the method now in use, that of providing each of his keys with a spring so arranged as to close the front contact at or before the time of interrupting the rear contact. This difficulty was, therefore, effectually removed as early as 1855. The second difficulty is a still more serious one, and arises in the following manner: In the simultaneous operation of the apparatus there must, of necessity, frequently be a change from a positive to a negative condition, or *vice versa*, of the line, and of the relays or receiving instruments, consequent upon the movement of a single key; yet it is evident that the reversal of the magnetic polarity of a receiving instrument by the action of one key must interfere with a signal which is being given upon it at the same time by the action of the other key. This difficulty is met with, in some form, in every arrangement of the receiving instruments. Stark employed three neutral relays, adjusted to varying degrees of sensitiveness, in one arrangement, and two polarized and one neutral relay in another, as did also Bosscha and Kramer. Bernstein used a single relay with three armatures, of varying adjustment. Neither Stark nor Siemens suggested any method of remedying this defect, and, judging from his published paper on the subject, the latter evidently considered it an insurmountable one. Bosscha, Bernstein and Kramer, by making use of different modifications of the same principle—that of operating the recording instrument or sounder by the opening of a shunt circuit as the first and last had already done with the main batteries, and by working from the rear instead of the front contact of the receiving relay—theoretically succeeded in surmounting this obstacle. Practically, however, the method of operating a register or sounder by closing and breaking a shunt is a very unsatisfactory one. It not only exhausts the local battery with great rapidity, but the demagnetization of the iron cores takes place with far less rapidity when the battery is cut off by a shunt, even of very small resistance, than when it is completely interrupted by breaking the circuit in the usual way, and this renders it impossible to receive and record the telegraphic signals with the rapidity that is necessary in modern telegraphy.

When these methods came to be tried on lines of a length exceeding 100 or 150 miles, the interference of the static discharges was superadded to the already existing difficulties, and for these reasons the results were, on the whole, so unsatisfactory that the subject remained in abeyance for many years. The subsequent labors of Schreder, Wartmann, Maron, Schaak and Zetzhe, between 1855 and 1865, though exhibiting great ingenuity and research, added little or nothing of practical value to what had already been done by the earlier inventors in the same field.

The revival of the duplex system in America, and

Electro-Harmonic System of Multiple Transmission.

During the past two weeks, Mr. Elisha Gray of Chicago, Ill., has been exhibiting his electro-harmonic apparatus in the Western Union Building, in this city. More than a year since we published an article descriptive of this curious discovery, so far as it had been developed at that time. Since then Mr. Gray has devoted the greater part of his time to the perfection of the apparatus, and has already succeeded in producing some very remarkable results. Mr. Gray's earlier experiments disclosed the fact that composite tones were as easily transmitted over a wire as single notes, and from this discovery he developed a system of multiple transmission founded on this principle. The apparatus was tested experimentally on a wire between Boston and New York, on September 11, with very satisfactory results. Four separate communications were simultaneously transmitted from Boston, and copied from four sounders by a like number of receiving operators in New York. In the main the signals were perfectly received on all the instruments, the only apparent defect being a tendency to shorten them somewhat, a difficulty which can doubtless be overcome by a suitable modification of the transmitting apparatus.

The principle of the apparatus is a very simple one. The depression of each key sets a self-vibrating electrotome in operation, which is adjusted or tuned to vibrate at a certain rate, differing from that of any of the others, when under the influence of the electro-magnet controlled by its corresponding key. These several sets of electrical vibrations are transmitted through the circuit without interfering with each other, in the same manner that almost any number of different sets of sound waves may pass through the air without mingling. At the receiving station, each instrument is so adjusted as to respond to its own special sets of waves or vibrations without regard to others. By breaking and closing the circuit upon the transmitting electrotome, so as to form telegraphic signals, these are transmitted and taken up by the corresponding receiving apparatus.

It is not easy to fix a limit to the number of different communications that may be carried on over the same wire simultaneously, either in the same or opposite directions. The marked success which attended the operation of the principle through two hundred and forty miles of line, on September 11, seems to promise results in the future of the greatest value.—*Journal of the Telegraph.*

The Harmonic-Electric Telegraph.

The harmonic-electric telegraph invention (now commonly known as the telephone) of Mr. Elisha Gray, of Cleveland, is undoubtedly destined to prove a very useful and important one. On Friday of last week we saw four despatches transmitted simultaneously from Boston to this city, on one of the Western Union wires. It is believed, and with good reason, that at least sixteen messages can by this invention be transmitted simultaneously over a single wire. Mr. Gray has made a discovery and invention which will be likely eventually to revolutionize the present Morse telegraph system.—*The Telegrapher.*

its extensive introduction into practical use, both in this country and in Europe, resulting from the improvements of Joseph B. Stearns—notably his method of compensating the effects of the static discharge from the line by the application of the condenser, which was made known in the winter of 1871-2—once more turned the attention of electricians to the problem of simultaneous transmission in the same direction.

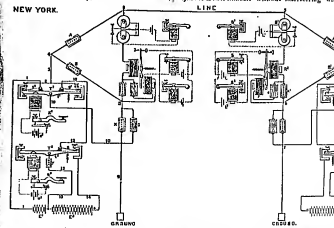
In a paper published in the *Philosophical Magazine* of June, 1873, Oliver Heaviside, of Newcastle-on-Tyne, England, pointed out, as Stark and Bosscha had done before him, that the invention of a system of simultaneous transmission in the same direction furnished at the same time the solution of the problem of quadruple transmission. He says: "It is theoretically possible to send any number of messages whatever simultaneously and in the same direction upon a single wire. Now, by combination with a null duplex system it becomes obviously possible to send any number of messages in the other direction while the opposite correspondences are going on, and without interference. Thus the working capacities of telegraphic circuits may be increased indefinitely by suitable arrangements. * * * From experiments I have made I find it is not at all a difficult matter to carry on four correspondences at the same time—namely, two in each direction, and if we may suppose the growth of telegraphy will be as rapid in the future as it has been in the past, it seems not improbable that multi telegraphy will become an established fact."

During the summer of 1874, T. A. Edison, of Newark, N. J., while engaged in conjunction with George B. Prescott, electrician of the Western Union Telegraph Company at New York, in experimenting upon Stearns's duplex apparatus, with a view of introducing certain modifications and improvements therein, devised a system of simultaneous transmission in the same direction which differed materially in principle from any of its predecessors, and which was destined to furnish the basis of the first practical solution of the curious and interesting problem of quadruplex telegraphy.

The distinguishing principle of this method consists in combining together two distinct and unlike methods of single transmission in such a manner that they may be carried on independently upon the same wire, and at the same time, without interfering with each other. One of these methods of single transmission is used principally in England, where it is known as the double current system, and the other is the single current or open circuit system, used on the continent of Europe. In the double current system the battery remains constantly in connection with the line at the sending station, its polarity being completely reversed at the beginning and at the end of every signal without breaking the circuit. The receiving relay is provided with a polarized or permanently magnetic armature, but has no adjusting spring, and its action depends solely upon the reversals of polarity upon the line, without reference to the strength of the current. In the single current system, on the other hand, the transmission is effected by closing and breaking, or increasing and decreasing the current, while the relay has a neutral or soft iron armature, provided with a retracting spring. In this system the action depends solely upon the strength of the current, its polarity being altogether a matter of indifference.

It will therefore be apparent that, by making use of these two distinct qualities of the current, viz., polarity and strength, two sets of instruments may be operated at same time on the same wire. This method possesses, moreover, the important practical advantage that the action of each of the two receiving relays is perfectly independent. Each receiving operator controls his own relay, and can adjust it to suit himself without interfering with the other—a peculiarity that none of the former methods possessed. As soon as this method was practically worked out, it became at once obvious that any of the different methods of simultaneous transmission in opposite directions already in use might be applied to it, as Stark, Bosscha, and others had long ago pointed out, the result of which would be a practical system of quadruplex transmission. This was shortly afterwards done upon the lines of the Western Union Telegraph Company between New York and Boston, a distance of 240 miles, and both the bridge and the differential system of duplex working were tried in combination with it with excellent results. When, however, the apparatus was experimentally tested on a circuit of about 450 miles, the effects of static induction became very strongly marked, and it was found that these could be more conveniently compensated in the bridge than in the differential system. The former was, therefore, decided upon as being better suited to the usually existing conditions than the latter.

The diagram shows the quadruplex apparatus as arranged upon the bridge plan.



T1 is a double current transmitter or pole-changer, operated by an electro-magnet, local battery e1, and finger key K1, in a manner well understood. The office of the transmitter T1, is simply to interchange the poles of the main battery E1 with respect to the line and ground wires, whenever the key K1 is depressed; or, in other words, to reverse the polarity of the current upon the line by reversing the poles of battery E1. By the use of properly arranged spring contacts, s1 s2, this is done without at any time interrupting the circuit. Thus the movement of the transmitter T1 cannot alter the strength of the current sent out to the line, but only its polarity or direction. The second transmitter T2 is operated by a local circuit, and the key K2 in the same manner. It is connected with the battery wire 12 of the transmitter T1 in such a way that when the key K2 is depressed the battery E1 is enlarged by the addition of a second battery E2, of two or three times the number of cells, by means of which it is enabled to send a current to the line of three or four times the original stength, but the polarity of the current with respect to the line of course still remains as before under control of the first transmitter T1.

At the other end of the line are the two receiving instruments R1 and R2. R1 is a polarized relay with a permanently magnetic armature, which is deflected in one direction by positive and in the other by negative currents, without reference to their strength. This relay consequently responds solely to the movements of key K1, and operates the sounder S1 by a local circuit from battery L1 in the usual manner. Relay R2 is placed in the same main circuit, and is provided with a neutral or soft iron armature, and responds with equal readiness to currents of either polarity, provided they are strong enough to induce sufficient magnetism in its cores to overcome the tension of the opposing armature spring. The latter, however, is so adjusted that its retractile force exceeds the magnetic attraction induced by the current of the battery E1, but is easily overpowered by that of the current from E1 and E2 combined, which is three or four times as great. Therefore the relay R2 responds only to the movements of key K2 and transmitter T2.

The same difficulty which had baffled former inventors arises, however, in this connection. When the polarity of the current upon the line is reversed, during the time in which the armature of R2 is attracted to its poles, the armature will fall off for an instant, owing to the cessation of all attractive force at the instant when the change of polarity is actually taking place, and this would confuse the signals by false breaks if the sounder were connected in the ordinary way. By the arrangement shown in the figure, the armature of the relay R2 makes contact on its back stop, and a second local battery, L2, operates the receiving sounder S2. Thus it will be understood that when relay R2 attracts its armature, the local circuit of sounder S2 will be closed by the back contact of local relay S; but if the armature of R2 falls off it must reach its back contact and remain there long enough to complete the circuit through the local relay S, and operate it before the sounder S2 will be affected. But the interval of no magnetism in the relay R2, at the change of polarity, is too brief to permit its armature to remain on

The Quadruplex Controversy.

WASHINGTON, April 18, 1875.

The Edison quadruplex telegraph controversy has assumed a new phase. Mr. Edison originally assigned an interest in his invention to George B. Prescott, and a joint application was made for a patent. Mr. Prescott agreed to assign to the Western Union Telegraph Company his interest in the patent, but the Automatic Telegraph Company claimed the whole benefit of the invention through a contract with Mr. Edison. An application was made to the Secretary of the Interior to induce him to overrule the decision of the Commissioner of Patents, and to make Mr. Edison the sole patentee. The appeal was made by George Harrington, who also claims to be Mr. Edison's assignee. His counsel, W. E. Chandler and J. H. B. Latrobe, contended on Friday that the Secretary had jurisdiction in this case. Gen. Butler, counsel for Mr. Edison, insisted that the patent should issue to his client alone on the ground that, whatever may have been his arrangement with Mr. Prescott, it was in the nature of a partnership, which had been dissolved by the withdrawal of Edison without having received a dollar from Mr. Prescott for any interest in it. The patent should not be granted to Messrs Edison and Prescott conjointly, as the Commissioner of Patents recently ordered, but that it should be issued to Edison, leaving any equities which might be claimed to exist by virtue of assignments to be adjudicated by the courts. Senator Conkling replied at once, raising the question of the Secretary of the Interior's jurisdiction over the matter. He contended that the decisions of the Commissioner of Patents are absolutely final as to all purely executive questions. He denied that the Secretary of the Interior had any jurisdiction whatever over any question relating to patents.

Gen. Butler and Leonard Meyers replied by citing decisions of the Supreme Court and the usage of the Patent Office respecting the nature of assignments. Secretary Delano in postponing his decision, said: "I recognize the fact that to the Commission is intrusted in the first instance, the duty of examining and deciding upon all questions that arise before him in his office, and are presented to him; but I am unable to bring my mind to the conclusion that it would be my duty to sign a patent, because in his best judgment he had directed it to be issued, if I, on the evidence in the case as presented to me, should be of the opinion that his conclusions were clearly and distinctly erroneous." In conclusion, Secretary Delano informed the counsel that he would allow fifteen days for the preparation of printed arguments on the merits of the case on the record, after which ten days further time would be allowed for counsel to file replies in briefs.—*N. Y. Tribune.*

from page 41.

its back contact long enough to affect the local relay S, and through the agency of this ingenious device the signals from K2 are properly responded to by the movements of sounder S2.

By placing the two receiving instruments R and RI in the bridge wire of a "Wheatstone balance," according to Stearn's patent of Nov. 12, 1872, and duplicating the entire apparatus at each end of the line, the currents transmitted from either station do not affect the receiving instruments at that station. Thus in figure 1 the keys K1 and K2 are supposed to be at New York, and their movements are responded to only by the receiving relays R1 and R2 at Boston. The duplicate parts which are not lettered operate in precisely the same manner, but in the opposite direction with respect to the line.

In applying this system of quadruplex transmission upon lines of considerable length, it was found that the interval of no magnetism in the receiving relay R2 (which, as above stated, takes place at every reversal in the polarity of the line current), was greatly lengthened by the action of the static discharge from the line, so that the contrivance of the local relay S was not sufficient to overcome the difficulties arising therefrom. A rheostat or resistance, X1, was therefore placed in the bridge wire with the receiving instruments, R1 and R2, and shunted with a condenser c, of considerable capacity. Between the lower plate of the condenser and the junction of the bridge and earth-wire an additional electro magnet, r, was placed, acting upon the armature lever of the relay R2, and in the same sense. The effect of this arrangement is, that when the current of one polarity ceases the condenser c immediately discharges through the magnet r, which acts upon the armature lever of relay R2, and retains it in position for a brief time before the current of the opposite polarity arrives, and thus serves to bridge over the interval of no magnetism between the currents of opposite polarity.

It will be seen that the combination of transmitted currents in this method differs materially from any of those used in previous inventions. They are as follows:

1. When the first key is closed and the second open............................. —1
2. When the second key is closed and the first open.................. +3 or +4
3. When both keys are closed.... —3 or —4
4. When both keys are open.............. +1

Here we discover another very important practical advantage in the system under consideration, which is due to the fact that the difference or working margin between the strength of current required to produce signals upon the polarized relay and upon the neutral relay respectively may be increased to any extent which circumstances render desirable. Within certain limits, the greater this difference the better the practical results, for the reason that the range of adjustment of the neutral relay increases directly in proportion to the margin. The ratio of the respective currents has been gradually increased from 1 to 2 to as high as 1 to 4, with a corresponding improvement in the practical operation of the apparatus.

over

From what has been said, therefore, it will be seen that before it became possible to produce a quadruplex apparatus capable of being worked at a commercial rate of speed upon long lines, it was essential that its component parts should have arrived at a certain stage of development. When in the early part of 1872 simultaneous transmission in opposite directions was for the first time rendered practicable upon long lines by the combination therewith of the condenser, the first step was accomplished. It now only remained to invent an equally successful method of simultaneous transmission in the same direction, which, as we have seen, was done in 1874.

administer to the wants of the public. The whole operating department can be seen on entering the Broadway door. The ladies department is at the Broadway end of the room and the switch is at the extreme west. Mr. S. H. Edwards presides at this handsome piece of mechanism. It contains 111 wires and is capable of hold two or three hundred loops. It was designed by President Eckert and manufactured by L. G. Tillotson & Co., of this city, who completed it in six days from the date of the order. The office contains fourteen quartette tables, eleven perforating instruments and eight automatic transmitters which are used only to the prominent points. There are about seventy employees in this department, sixteen of whom are ladies. All of the male employees are required to wear single breasted blue coats while on duty. Those of the managers and chiefs are double breasted that their rank may be readily distinguished. The neatness of the men is in keeping with the fitting of the room, and together they present a very pleasant appearance. The room is well ventilated making it a fine healthy office. On the whole the office is what has long

QUADRUPLEX TELEGRAPHY.

"We are not aware," says the editor of the London *Telegraphic Journal*, "that a quadruplex circuit exists in England at present, although we are assured that since 1874 quadruplex telegraphy has been an established fact in America, and that its employment there has been eminently successful. Statistics are nevertheless wanting to establish its practical value."

* * "We seem to be still as much in the dark as ever to the real advantages of quadruplex telegraphy. Without entering at all minutely into the system, it is sufficient to state that the difficulties inherent in the adoption of quadruplex telegraphy are greater than at first sight would be imagined."

* * "Working a quadruplex system—that is, four circuits upon one wire—to meet the requirements of busy centers of commerce, looks very much like intrusting too many of the eggs to one basket, and in the event of interruptions could not fail to be attended with the most serious inconvenience."

June 16/77

For the information of our valued British cotemporary, we would state, by way of statistics, that the Western Union Telegraph Company is now regularly operating, daily, by the quadruplex system, about twenty thousand miles of its wires. The lines between New York and all the large cities, as Boston, Philadelphia, Pittsburgh, Chicago, St. Louis, Washington, New Orleans, are worked by the quadruplex plan.

For the illumination of our cotemporary, we would state that the real advantage of quadruplex telegraphy is that it permits the sending of four messages over one wire during the time heretofore required for sending one message by the old method. In other words, as much business may be done over one wire, by the quadruplex, as can be done over four wires by the common plan.

There are no inherent difficulties about the adoption of the new system in England. All that is needed is to send over to New York a postal money order and pay for as many instruments as are wanted, and then set them to work. They will work just as well in London as here.

To stand in the gallery of the great operating room of the Western Union Company, in this city, and gaze upon the multitude of operators there daily at work with the quadruplex instruments, does indeed seem like looking upon a good many eggs in one basket; but we hear of no inconvenience or interruptions therefrom resulting. On the contrary, so great is the regularity and necessity for the new system that the business of the Western Union could not now be transacted except for the quadruplex, the use of which is being rapidly extended. Finally, we suggest to our cotemporary that he make a summer excursion over here and learn something about modern telegraphy. The absence of the quadruplex in England shows conclusively that his countrymen are several telegraphic generations behind the age.

44

DUPLEX TRANSMISSION WITH TWO RELAYS.

July 15 1880 — Telegraphic Journal

By M. KOVACEVIC, Secretary of the Telegraphic Administration at Agram.

The employment of two relays for duplex transmission has for its object the avoidance of the necessity of establishing equilibrium, an indispensable condition with a single relay, and to give the means of obtaioing duplex or diplex transmission without other means than those which are required for ordinary simple working.

It is possible to obtain this object in different ways, and the arrangement depends upon the disposition of the batteries, that is to say, whether like or uolike poles are put to earth at the two stations.

I.

Arrangement of Terminal Stations.

Fig. 1 shows the arrangement to effect duplex working io the first of these two cases, that is to say, wheo the batteries at the two stations have similar poles to earth, and when, consequently, the polesact against one another. The transmitting keys are of the ordinary kind, baving their axes connected to the two relays of each station, and the working contacts to the batteries, of equal power, B, and B,, and to earth.

R, and R,, are neutral relays, which can, however, be also polarised relays. The relays, P, and P,, on the contrary, must oecessarily be polarised so that they may be acted upon only by the current coming in through the line, W, and oot by a current going out to the same.

The figure shows clearly how communication is established with the local batteries, L, and the Morse writers, M, and M,, by means of the relays, P, and R,, on the one hand, and the relays, P,, and R,, on the other. The closing of the local batteries and, consequeotly, the production of signals oo the Morse writers cao only take place when the armatures of the polarised relays remaio in contact with the screws, u,, and when, on the contrary, the levers of the neutral relays are in commuoicatioo with the lower screws, v,.

The condition iodicated io the figure is the state of repose, during which the batteries, of equal power, B, and B,, which communicate with earth by their negative poles, send their positive currents out to the line, W, or produce a neutral effect.

The levers of the neutral relays remain free, and rest in contact with the lower screws, v,, whilst the armatures of the polarised relays establish communication with the screws, u,.

In this case, neither of the Morse writers produce signals, the circuit of the local batteries, L, not being closed.

If the station, I, depresses his key, the positive current of the battery, B,, passes through the relay, R,, and returns by the point, a, to the negative pole, by the axis and the working contact of the lever of the depressed key.

The resistance of this latter path of departure by the point, a, which can be formed of short and thick iron wires, being nil, it does not produce any bifurcation, and, consequently, it does not allow any of the current of the battery, B,, to pass out to the line, W.

The relay, R,, at the station, I, which sends signals, works when its lever is moved away from the screw, v, and goes over to the screw, v,. The Morse printer, M,, produces then its proper signal, if the armature of the polarised relay, P, remains in contact with the screw, u,, but such is not the case, as will be seen.

By the fact of the introduction of the battery, B,, in the closed local circuit, the battery, B,, of the station, II, is the only one which works to line. Its positive current passes through the two relays, R,, and P,, of the station, II, by the line, W, the polarised relay, P,, of the station, I, from whence it arrives at the point, a, by the lever of the key at the station, I, which has been depressed, and by this means goes to earth. The relay, R,, comes into action when its lever leaves the screw, v, and makes contact with the screw, v,. On the other hand, the polarised relay, P,, does not work, for the northern magnetism being increased in the lower coil and increased in the upper coil, the contact of the armature of the relay with the lower screw, u,, is only made stronger.

The local battery, L, has its circuit closed through the medium of the levers of the two relays, P,, and R,, and thus the Morse writer, M,, reproduces the signal sent out by the station, I.

The positive current of the battery, B,, which goes through the polarised relay, P, of the station, I, increases the northern magnetism in the upper coil, whilst it decreases it in the lower coil. The armature of this relay leaves then its contact with the screw, u,, and that before contact is established with the screw, v,, of the relay, R,, when the key is depressed.

The circuit of the local battery, L, of the station, I, remains open, and consequently, the Morse writer, M,, does not reproduce the signals.

The same thing occurs when station II depresses his key whilst the key of station I remains in its normal position. As, in this case, the current of the battery, B,, is the only one which goes out to line, the relay, R,, comes into action while P, remains inactive. The local battery, L, of the station, I, is then closed, and the Morse writer, M,, reproduces the signal sent out by station II.

When the positive current of the battery, B,, which goes out to line, has broken the contact of the armature of the polarised relay, P,, with the screw, u,, the circuit of the local battery, L, of the station II becomes open, although the relay, R,, of that station works by its own current, which finds a closed local circuit from the point, b, through the depressed key.

If the two stations depress their keys, the relays R, and R, are worked by their own currents introduced in the local closed circuit.

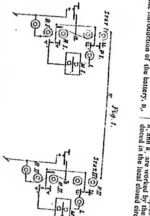


Fig. 1.

The polarised relays, P, and P,, not being, at this moment, acted upon by any current, their armatures continue resting against their contact screws, u; and in consequence, the circuits of the local batteries are closed and the Morse writers respond.

If the station, I, allows his key to return to its normal position, his Morse writer continues to work, the levers of the relays, R, and P,, remaining in contact with the screws, v, and u,. On the other hand, the signals sent out by the station, I, cease to be reproduced by the Morse writer, M,, for the contact of the tongue of the relay, P, with the screw, u, becomes then interrupted by the current of the battery, B,, coming to line, and the circuit of the local battery, L, becomes opened.

If the station, II, also allows his key to come back to its normal position, the effects of the currents from the batteries, B, and B,, neutralise one another and produce again the state of rest which has been previously referred to, and therefore the station, I, ceases also to reproduce the signals emitted by the corresponding station.

If leakages or changes of resistance occur on the line, the effects of the currents are only to produce partial compensation, and each section of the line

The Operator.

The Telegraph Operators' Journal.

Vol. II. OCTOBER 1, 1874. No. 3.

DUPLEX—No. II.

There is an extra phenomenon in the electrical duplex which does not occur in the water device. This is electrostatic induction, the effect of which is to destroy the balance of currents in the coils of the differential relay.

In sending a dash, for instance, through the relay to the distant station, the static inductive current is added to that of the battery current, thereby increasing the strength of the first portion of the signal within the main line helice, while the artificial line, being free from these currents, is not thereby increased. Hence the cores of the differential relay will become magnetic by this excess of current, and the lever will be attracted for an instant only, or "kick," as the operators say.

On disconnecting the battery a static current flows from the line in a contrary direction to the first current, and this again produces a movement of the relay lever.

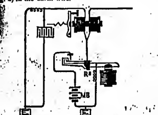
Now, it follows that if we could by any means create a static induction current upon the artificial line, equal to that of the main line, at the moment the battery is connected and disconnected from both circuits, that the two currents would balance each other in the differential relay.

Mr. Stearns was the first to bring about this necessary result, and without which previously devised apparatus were impracticable on lines of ordinary length. Mr. Stearns effected it by adding a condenser to the artificial line.

A condenser consists of a number of sheets of tin foil or other metallic surfaces, connected to the artificial line, and facing an equal number of plates connected to the earth. These plates are separated from each other by sheets of insulating material, usually paper dipped in boiling paraffin.

If the main line is very short, as between New York and Philadelphia, the strength of the static induction currents are insufficient to produce a movement of the relay lever and the condenser is unnecessary; but when the line is long, as between New York and Buffalo, the static induction is sufficient to prevent all signalling until the condenser is added to the artificial line, and then it is requisite that a large number of sheets are used, otherwise it will not set up currents of sufficient strength to maintain the balance.

Another essential device to obtain perfect signalling is the addition of a small resistance coil. R 2 (fig. 2) in the earth wire.



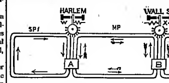
This coil has a resistance equal to that of the battery, so that if either be made to form part of the main line the resistance will be constant. It also serves to reduce the spark which occurs when the battery is for an instant "short-circuited" by the signalling point and spring. Were no coil inserted in the earth wire the resistance of the main line would be increased when the battery was inserted, and decreased when put to earth. This variation in the resistance of the line would vary the strength of the received signals. If the battery was inserted the distant signals would be "light," and when disconnected they would be heavy; and when the received current was exceptionally weak it would prevent signalling altogether, if the battery resistance was considerable.

The spark, if a grove battery is used, would quickly destroy the contact points on the sounder lever. This device is also due to Mr. Stearns.

With these exceptions the electrical and water duplex are alike.

One peculiarity of the duplex is, that it may be operated when the signalling batteries are connected to the line in such a manner that they oppose each other, *i. e.*, when the positive pole of each battery is connected to line. When this takes place, no current passes over, but the current circulating within the artificial lines keeps the relays closed.

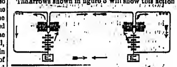
The water duplex diagram, slightly changed, will show this action clearly:



When no water passes from the reservoir A through the main or secondary pipes, the water from B passing through M P, throws the lever of W to the left, and the local circuit is closed, so to speak; but, as explained before, the wheel X remains unaffected. If, now, the water is made to pass from A into the main and secondary pipes, in the direction indicated by the unfeathered arrows, it will act, or we will suppose it to act, against the other stream passing in a contrary direction, in such a manner that the water will become still or cease to flow. The effect of this would be to allow the lever of W to be drawn to the right by the spring, were it not for the fact that now instead of the lever being held by the water from B the water in the secondary pipe, SP 1, performs this operation. If the water ceases from A, the balance between the two streams in the main pipe is destroyed; the water ceases in SP 1, but the lever will still be held against the point on the left by the water from B. It will be seen that when the two streams oppose each other, the wheels and levers are held to their forward points by the water in the equating pipes, while if only one stream is passing they are held by the water in the main pipe.

If the direction of the water in the main pipe is the same, then all the signalling is done by these currents only and independent of the equating circuits.

The arrows shown in figure 3 will show this action



in the electrical duplex. When both stations connect the battery to line they oppose each other, and no current passes over it but the relays close, nevertheless; for the current in the coils on the artificial lines, not being balanced by an equal amount flowing through the main line coil, closes the relay; when the batteries have their dissimilar poles connected to line, a current flows and the relay is closed only by the main line current.

It has been found in practice, that if a relay be inserted in a wire worked duplex, the balance is destroyed.

The reason for this is, that the passage of the signalling current through the coils of the relay sets up secondary magnetic inductive currents (these currents are distinct from static induction currents), the effect of which is to weaken the main current on closing and sending a current in the same direction after the battery is disconnected.

This effect, which is absent from the artificial line, destroys the equation. If a relay of the same character be inserted there the balance is preserved.

In fact, if all the evil effect which take place on the main line could be produced upon the artificial, the equation would be maintained and perfect signaling would always be obtained.

There are many effects produced on the main circuit which are not produced upon the artifical, among which may be mentioned.

1st. Static Induction.

2d. Magnetic Induction, as from relays.

3d. The induction from other wires.

4th. The phenomenon of secondary battery action.

5th. Leakage.

6th. A permanent current from the other wires.

7th. Variability of leakage, caused by opening other wires which acts as earth connections.

8th. Variability of the electrostatic capacity by opening and closing wires in close proximity.

9th. Momentary currents from other wires by leakage across the arms.

10th. The variability of leakage by increasing and decreasing the strength of the signaling currents.

11th. Lightning.

12th. Auroral currents.

13th. The difference between the electrostatic capacity of the wire at noon and midnight.

There are other causes which prevent perfect signaling to be found in the various instruments, among which may be mentioned the following:

46

Decision of the Secretary of the Interior Against the Professor of Duplicity and Quadruplicity and Mr. Harrington.—Sharp Practice of ex-Secretary Delano.

IN THE TELEGRAPHER of April 24, 1875, we gave an account of an appeal to the Secretary of the Interior by Mr. GEO. HARRINGTON, from the decision of the then Commissioner of Patents on the *prima facie* title to the quadruplex patents, so called (which T. A. EDISON had applied to have issued to himself and Mr. GEO. B. PRESCOTT as assignees, but which application he subsequently attempted to withdraw, and asked that they should be issued to himself and HARRINGTON), that they should be issued, as first requested, to EDISON and PRESCOTT, leaving HARRINGTON to establish his claims to them, if he had any, in a Court of Equity. Patents, when issued, are required to be signed by the Commissioner of Patents, and countersigned by the Secretary of the Interior. Who HARRINGTON asked, and what the professor of duplicity and quadruplicity tried to aid him in obtaining, was that the Secretary should refuse to sign the patents when ready to be issued to EDISON and PRESCOTT. A hearing was had on the appeal, and the Secretary declined to give a decision on the main question of the title to the patents until they were presented to him for signature. In the meantime he directed the Commissioner to send up to him all the papers in these cases, and *held them until he went out of office*, unbeknown to Mr. PRESCOTT, thus making any action on the applications impossible.

When the present Secretary, Hon. Z. CHANDLER, came into office, and as soon as he could get time to look into the matter, he returned the papers to the Commissioner of Patents for further action, with the following decision on the appeal of HARRINGTON, which effectually checkmates one of the little games of the professor of duplicity and quadruplicity and his associates.

It should be known, however, that while these applications were, by what certainly appears to be very sharp practice on the part of Mr. DELANO, withheld from possibility of action, Chief Examiner WILBER, of the Electrical Division of the Patent Office, allowed EDISON to amend an old application known as Case H, and incorporate in it a vital part of the invention in one of the suspended applications, which the Commissioner had decided should issue to EDISON and PRESCOTT, and on the last day of the late Commissioner's official connection with the office had the amended patent issued to EDISON, who subsequently assigned it to HARRINGTON. This was so evidently a fraud upon Mr. PRESCOTT's rights, and in such direct opposition to the previous order of the Commissioner, that Mr. PRESCOTT is now prosecuting the Examiner before Mr. DUELL, the present Commissioner of Patents therefor.

After reciting the history of the case and the points contended for, and on which a decision was asked by the respective parties, the Secretary says:

I have considered the very able and exhaustive arguments of the learned counsel for the respective parties with great care, and have reached the conclusion that the action of the late Secretary in arresting the proceedings before the Commissioner was premature, in any view of the case, and not consonant with good practice and the orderly conduct of business in your office.

I might stop at this point and return the papers without considering the principal question, as to the power of the Secretary of the Interior to revise the decisions of the Commissioner of Patents; but in view of its importance, and the very full arguments thereon by counsel for the respective parties, I deem it proper to express my opinion upon this question also.

No appellate jurisdiction in cases like this is conferred upon my office by any express statute. The grant of power from which it is sought to be inferred is found in secs. 441, 481 and 4883, R. S. Sec. 441 is as follows:

"The Secretary of the Interior is charged with the supervision of public business relating to the following subjects: * * Fifth, patents for inventions."

Section 481 provides that "the Commissioner of Patents, under the direction of the Secretary of the Interior, shall superintend or perform all duties respecting the granting or issuing of patents directed by law."

Sec. 4883 provides "that all patents shall be issued in the name of the United States of America, under the seal of the Patent Office, and shall be signed by the Secretary of the Interior, and countersigned by the Commissioner of Patents."

That a grant of supervisory power has not been intended by Congress to include an appellate power I think is evident.

In defining the power of the Secretary of the Interior with respect to the census, it provides that he "shall exercise supervising and appellate powers in relation to all acts of marshals," &c., R. S., sec. 443. So, in sec. 441, above cited, the same supervision is given of public lands as of patents; yet the right of appeal to the Secretary is expressly granted by sec. 2273, R. S., in cases of contest for the right of preemption.

And in the act of March 3, 1849, for the establishment of this Department, it is provided "that the Secretary of the Interior shall exercise and perform all the acts of supervision and appeal in regard to the office of Commissioner of Patents now exercised by the Secretary of State."

Nor does the statute which provides that the Commissioner of Patents shall superintend or perform all duties respecting the granting and issuing of patents under the direction of the Secretary of the Interior confer upon the latter office any appellate power. The power to supervise includes the power to direct.

Supervision is the act of overseeing, of superintendence—is concurrent with, and accompanies the official action which is its subject, and is applicable to executive duties.

To appeal is to move from a lower to a higher jurisdiction for review of judicial action, and necessarily *follows* such action.

The provision of the act of 1849, above cited, was repealed by the act of July 8, 1870; but I am unable to learn that any appellate jurisdiction has ever been exercised or claimed by any Secretary of State or of the Interior Department over the judicial action of the Commissioner of Patents since the creation of the office by act of July 4, 1836.

An ample remedy against the consequences of an erroneous decision of the Commissioner is provided by appeal to the Supreme Court of this District, or by bill in equity, as the case may be.

For the reasons above suggested, I am of the opinion that no power is vested in me to review the decisions honestly made by the Commissioner of Patents in cases within his jurisdiction, and I return herewith all the papers relating to the applications above mentioned, in order that due legal proceedings may be had thereon in your office.

Very respectfully, your obt. servt.,
Z. CHANDLER, *Secretary*.

To the Commissioner of Patents.

In the November *Scribner* is an article—with portrait of Edison—on the latter's system of quick telegraphy, which was put in practice eight years ago, transmitting over a single wire several thousand words per minute for the twenty-five usually sent by the Morse machine.

The Plumber and Sanitary Engineer

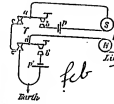
J. E. H. asks: How is it that telegrams n sent two ways over one wire at the same ? A. The instruments are so arranged that urrent sent does not affect the receiving inent of the station sending. This is effected rious ways. One of these consists in winding magnets with double coils, the convolutions hich are put on oppositely; or the connections so made that the result amounts to the same g. One end of one coil is connected to the wire; one end of the opposite coil, to the und, through a resistance equivalent to that of line; and the other ends of the coils are joined ther. The junction is then connected to the nsmitting apparatus. When a current is sent t divides where the two coils meet, half pass through one coil to the line, the other half, rough the opposite coil and resistance, to und. As the half currents are oppositely dicted in the two coils, the action of one neutral that of the other, and the iron cores remain polarized. The half current which goes to line sses on to the receiving instrument of the disnt station, and, if the key at that point is open, es through one coil of the instrument, thus proing a signal. There may also be a time, in siltaneous transmission, when the received half rent passes through both coils of the home inment. It will be observed, however, that, for h a case, the convolutions of the coils supplet each other; but at the same time, the curt must pass through the extra resistance, so that, le the number of convolutions is doubled, the rrent is reduced one half by this added resistnce, and thus the effect remains before.

SIMULTANEOUS TRANSMISSION IN OPPOSITE DIRECTIONS.

By M. GIOVANNI MAIANI, of the Italian Telegraphic Administration.

THE system of double transmission that I am about to describe is based upon the following principles: A relay with two bobbins is fixed to a permanent magnet in such a way that the armature acts by repulsion, and not by attraction. The wire of one of the bobbins is distinct from the wire of the other bobbin, and the two wires thus form two distinct circuits—the one a local circuit, the other a line circuit. The soft iron cores of these two bobbins of the relay are fixed, the one to the north pole and the other to the south pole of a permanent magnet. The transmitting key is of the ordinary Morse form, very slightly modified; to the front part of it two contacts insulated from one another are added, which serve for the two circuits above mentioned. These contacts should be so adjusted that by the movement of the key they should make or break contact exactly at the same moment.

The figure represents the arrangement of this system of double transmission. R represents the relay, N the bobbin with the north pole, S the bobbin with the south pole, T the double key, a and a' the two levers of the key, formed of little flat springs, to which springs the two outer ends of the wires of the bobbins are connected; c and c' are two metallic contacts fixed at the extremities of the levers and in connection with the earth. In the normal position of this double key the levers rest on these contacts, and are thus in



feb 78

connection with the earth; b and b' are two little metallic plates connected to the positive poles of two batteries—the local battery p and the line battery p'. The connections being thus arranged, the following results are obtained:

It is first of all necessary that the strength of the local battery, which sends a current through the south pole bobbin, be so regulated that it may transmit a current exactly equal in power to the one sent out by the line battery through the wire of the other bobbin and out to line to the corresponding instrument at the further station. This equality can be arrived at by observing the deviations given by a good galvanometer, which can be switched either into the line or the local circuit—the battery of the latter being varied, so that the deflections in both cases are the same. When the batteries are in good condition this equilibrium may be maintained for several days unless accidental circumstances interfere.

For a line of a given resistance the relation between the local and line batteries is in the proportion of about 1 to 8. If, now, the key at one station be depressed, the levers a a' are put simultaneously in communication with the contacts b b' and at the same instant the communication of the levers c c' with the earth is interrupted. The current of the local battery p traverses the south pole bobbins to get to earth, and produces in the soft iron core a contrary magnetism to that which is given it by the permanent magnet; that is to say, the current tends to diminish the attractive force of the core for the armature; but, at the same time, the current of the line battery p' traverses the north pole bobbin and out to line, and increases the attractive power of the core of that bobbin; for at the transmitting station this current produces in the soft iron core a magnetism equal to that which the local battery takes away, consequently the armature remains attracted against the poles.

At the other station, the arrival current entering by the outer extremity of the wire of the north pole bobbin goes to earth through the lever a' and the contact c', and produces in the soft iron core a magnetism contrary to that which is given it by the permanent magnet; the attractive force on the armature being thus diminished, the armature rises off the poles under the influence of an antagonistic spring. Immediately on the cessation of the current the core regains its magnetism, and the armature is again attracted.

Finally, if the keys at both stations are simultaneously depressed, the currents going out to line being equal and contrary, annul one another, and thus the north pole bobbins of the two relays are not influenced by the currents. The south pole cores, then, being both under the influence of the local batteries, have their magnetic powers diminished, and the armatures at both stations consequently rise.

If in this last position one station allows his key to rise, the current from that station ceases to be emitted by him; but the connection of the line wire to earth is not interrupted, and the armature, though no longer under the influence of the local current, but under the influence of the current from the other station, which current is no longer nullified, continues to remain detached from the poles of the magnet. But at the moment when there are no longer simultaneous currents on the line, the battery of the station which continues to keep his key depressed itself ceases to influence its own electro-magnet, and the armature at that station consequently rises.

Thus, then, the armature acts when the current arrives on the relay, or when the local battery is in action; but in these two cases, in order to detach the armature of the electro-magnet, it is sufficient simply to adjust it so that the strength of the arrival current is sufficient to diminish a little the magnetism imparted by the permanent magnet, and the armature then detaches itself from the cores by the influence of the antagonistic spring, and never by the action of the arrival or the local current.

When, on the contrary, the armature is attracted, this attraction always takes place in virtue of the same constant force of the magnet, which at the moment when the arrival current ceases on the relay, as on the line, restores magnetic power to the cores as much when the key of the station by which they are acted on is in its normal condition as when it is depressed. Under this condition the armature is always attracted by a permanent magnetic force of equal strength without undergoing in its movements any kind of change

47

OVER

44 48

which could prevent the correct reception of the signals. In the laboratory experiments this result can be obtained by the same form of key and with the same connections with an ordinary relay, or Morse ink-writer of sufficient resistance, provided the two bobbins are separate, so that the connections can be made in the manner which has been indicated.

But such is not the case on a line where, the armature of an ordinary relay being attracted irrespectively by the arrival and the local current, which are never equal (that of arrival being from the leakage on the line always less than the local current, which, as we have before said, is equal in strength to the departure current), would thus be affected either by the greater or by the less force, being thus able to remain continuously attracted if the spring is adjusted for the smaller current, or not being attracted at all if adjusted for the greater current.

In all these cases the movements of the armature would be very irregular, whence would result confused, broken, or weak signals.

It is for this reason that I have proposed for this system of transmission a relay with a polarized electro-magnet.—*Journal Telegraphique.*

July 78

The "duplex" method of telegraphy has been successfully applied to the Wheatstone automatic instruments, and on a recent occasion as many as 358 messages were sent in an hour by its means—219 in one direction, and 139 in the other. More than 139 could have been sent, but they were not received.

Dec 78

DUPLEX TELEGRAPHY.—Mr. Muirhead has recently successfully applied his duplex system of working telegraph lines to the cable from Madras to Penang, a length of 1300 miles. This extension of the system makes a total of about 10,000 miles of cable worked upon Mr. Muirhead's system, and we understand that, so far, it is the only successful method whereby long submarine cables are practically worked on the duplex principle. The Eastern Telegraph Company have for several years employed this system for working the traffic on all their trunk lines, and the latest extension, above referred to, carries the working as far east as Penang. Duplex telegraphy consists in a method of sending two messages on the same wire at the same time in opposite directions, and Mr. Muirhead's system was fully described in *The Times* about a year since.

Edison in Trouble.

NEW YORK July 23.—A Washington special despatch to the Graphic says: "Edison has a claimant for his quadruplex. H. C. Nicholson, a Kentuckian, professes that the machine involves principles which he originated. The case is being considered at the Patent Office, and if it is found that there appears to be any equity to the new claim, a hearing will be given to the matter. This machine is now one of the most elaborate and valuable in use in the telegraphing, and should Mr. Nicholson's claim be demonstrated, Mr. Edison's perquisites will suffer materially."

Newark Advertiser July 23 /78

AN ACCOUNT OF DUPLEX TELEGRAPHY

THE introduction of the duplex system of working not only upon land-lines, but on sub-marine cables, is without doubt the most important advance recently made in electric telegraphy.

Duplex telegraphy may be defined as the art of telegraphing in opposite directions simultaneously along one line wire.

It is claimed by M. Zantedeschi in papers read before the Academy of Sciences, Paris, in 1855, that as early as 1829 he had suggested and demonstrated the possibility of working "duplex;" but until the year 1853 there do not appear to have been any noteworthy attempts made to effect it practically. In that year, Dr. Gintl, a director of Austrian telegraphs, described a system of duplex telegraphy to the Academy of Sciences, Vienna, and practically tested it on the land-lines between Vienna and Prague.

The principle underlying this and all other systems, is that the outgoing currents at a station shall not sensibly affect the receiving instrument there, while, at the same time, the latter is free to be affected by the incoming currents, so to speak, from the other station. That is to say, no signals are made at a station by its own sending currents, unless when these are interfered with by the sending currents of the other station.

Gintl's plan was as shown in Fig. 1. The receiving instrument, R I, was wound by two separate wires, one long and thin, the other short and thick. The long wire, shown by a full line, was connected at one end to the line L, and the short wire, shown by a dotted line, was connected at one end to a local, or, as it was called, a "com-

pensating" circuit. Both of these wires were connected at their other ends to a signalling key or sending instrument, K, having duplicate points. Two batteries, B and B', one large and the other small, were also connected to this key in such a manner that on making contact the current from the larger battery B passed through the long coil of the instrument into the line, while at the same instant the current from the smaller battery B', passed through the short coil and compensating circuit. These two currents were so adjusted as to balance each other in their effects on the indicator of the receiving instrument, and no signal was therefore made by the outgoing or signalling current from the battery B. Such was Gintl's arrangement at both stations, S and S'. Confining our attention to any one of these stations, say S, we see that as long as only S is sending, the receiving instrument at that station is unaffected, but when S' is also sending at the same time, the currents in the line from S' must interfere with the currents in the line from S, either aiding or opposing these according to the poles of the battery which are applied, and thereby disturbing the balance of currents on the receiving instrument at S, causing it to make signals. And we see also that these signals are entirely under the control of S'—that when S' applies his battery to the line, S's instrument will make a signal, and that when S applies his battery to the line, S''s instrument will make a signal, or that when either put "earth" to the line, that corresponding "spaces" will be recorded. The currents do not cross each other in the line, as was sometime thought, but they interfere with each other in such a way as to disturb the electric balance which independently exists at either end.

One objection, however, to this plan of Gintl's was that the lever of the key during sending interrupted the line circuit when it was between the earth and battery contacts; and another more serious objection lay in maintaining the equivalence of the two currents, as the smaller battery working through the shorter circuit lost power more rapidly than the signalling battery.

Gintl, however, in the following year (1854) obtained better success with a Bain's chemical printing instrument. Here he made the two currents oppose each other upon the chemically prepared paper and no stain was produced by the outgoing current. The sending current from the other station neutralised to a certain extent the outgoing current and the *local* current then overmastering it stained the paper and produced signals.

Early in 1854, while Gintl was still engaged in experimenting with the Bain's instrument, a great improvement was effected on his plan by Herr Carl Frischen, a telegraph engineer of Hanover. Frischen dispensed with the second battery B' and split up the signalling current itself, causing one part to pass round one coil of the receiving instrument into the line and the other part to pass round the other coil of the instrument into the local or compensating circuit. Instead of making the two wires of the instrument dissimilar, like Gintl, he made them both alike, so that the instrument was practically wound by equal wires in opposite directions and thereby rendered *differential*. He inserted into the compensating circuit a rheostat or set of resistance coils whose resistance could be adjusted to equal the electric resistance of the line. His arrangement at either station is shown in Fig. 2. Here R I is the differentially wound receiving instrument, B is the battery, and R is the rheostat or artificial line as it was called, because of its being intended to imitate the actual line. K and E are as before, the sending key and earth plates respectively. In the act of sending a message, on making contact between the key and battery at *a* the current flowing into the apparatus divides itself at the point *b*, and part passes through the right coil of the instrument into the line, while part passes through the left coil into the local circuit. But the resistance of the local circuit being made equal to that of the line and the two coils of the instrument being electrically equal one *half* of the current will flow through one coil and the other *half* through the other coil. The coils being oppositely wound these currents will neutralise each other in their effect on the indicator or needle of the instrument and no signal will be produced as long as they flow freely. We have seen, however, that the sending of the remote station may either oppose or assist that part of the current entering the line. Thus the balance is disturbed and signals will be made on the receiving instrument of one *kind* or another according as the line current or the local current overbalance each other.

In sending by this method of Frischen's the line circuit is never completely interrupted, but it will be observed that according to the position of the key the line is either applied "to earth" direct or through the battery, or through the resistance R, and this leads to a troublesome variation in the signals.

Frischen's method was re-invented a few months subsequently by Messrs. Siemens and Halske of Berlin, who patented it in England, where, however, they were forestalled by a week by Mr. Stirling Newall, of Gateshead, whose patent bears date October 30, 1854. Newall describes substantially the method of Frischen-Siemens, and in 1855–56, successful experiments were made under his patent on the Manchester and Altringham line; but when he came to make trials upon the longer line between Birmingham and London, the *static* charge and discharge of the line was found to make false signals. Condensers or accumulators of electricity were applied to correct this disturbance with promising results, but the expense of constructing large condensers was objected to and their use was prematurely abandoned.

At this time there was a great deal of activity in the direction of duplex working displayed both at home and abroad. Besides the names mentioned, Messrs. W. H. Preece, Highton, De Sauty, and others in this country, Edlund, Bosscha, Kramer, in Germany, and Farmer, in America, were all more or less engaged in the work. In 1856 a good many lines were worked on the duplex principle in Prussia, but the time was not yet ripe for its successful introduction, and it gradually fell into disuse again. Some desultory activity was still shown here and there, however, showing that the idea had not been lost sight of. In 1862 Mr. William Hinckling Burnett patented a method of working two or even three distinct systems of telegraphy by the use of currents of different degrees of force, and in 1863 M. Maron, of Berlin, appears to have first placed the receiving instrument in the diagonal of a Wheatstone's balance. This has been called the Wheatstone bridge method in the recent revival of duplex, and it may be shown as follows, Fig. 3.

Here *r* and *r'* are two of the branch resistances of a Wheatstone's balance; the line and artificial line, or rheostat, R, forming the other two branches. The receiving instrument, R I, is inserted in the "bridge" wire. In sending, the current from the battery B splits at *b*, and part passes by *r* into the actual line, while part passes by *r'* into the artificial line. If *r* be equal to *r'*, and the actual line be equal to the artificial line, the current will divide itself equally, and the potentials, or, as it may be called, the electric levels, at *c* and *d*, will be equal, and there will be no tendency for a current to flow through the cross channel or "bridge wire," and the receiving instrument will not, therefore, be affected. When, however, the line currents are interfered with by the sending currents of the distant station, this balance will be disturbed, currents will flow through the "bridge wire," *c d*, and the receiving instrument will signalise. The resistance, *w*, may with some slight advantage be made equal to the battery resistance. It will be seen that in the balance method, as in the differential method, the principle consists in dividing the signalling current between two circuits whose electrical properties are practically the same,

E force électro-motrice de la pile de compensation.

α sa résistance intérieure.

K manipulateur de résistance constante. Le Dr. Gintl se servait d'un manipulateur ordinaire qui, la chose est claire, devait forcément échouer.

k manipulateur ordinaire; les deux manipulateurs d'une même station se meuvent simultanément, c'est-à-dire les contacts 4 et 5 sont établis et interrompus en même temps.

d, f et w différentes résistances.

a une des bobines de l'appareil différentiel, celle qui est combinée avec la ligne.

b l'autre bobine intercalée dans le circuit de compensotion. Par a et b sont aussi désignées les résistances respectives de ces deux bobines.

Les bobines a et b, avec leurs piles e et E, sont disposées de façon à produire des effets magnétiques opposés par rapport au même pôle-magnétique. Dans chaque station, les deux circuits (le circuit de ligne et le circuit de compensation) sont isolés l'un de l'autre. Toutes les autres lettres, comme L, L', L'', etc., ont la même signification que dans les articles antérieurs.

La méthode de compensation a deux défauts principaux que ne présentent pas les deux méthodes précédentes.

Primo: Le succès de la télégraphie Duplex par la méthode de compensation dépend de la possibilité de fermer et d'interrompre simultanément deux contacts différents (4 et 5). Le Dr. Werner Siemens a démontré la difficulté mécanique que présente une solution satisfaisante de ce problème et c'est, en fait, une des raisons qui l'ont amené à proposer la méthode différentielle.

Secondo: La balance dans chaque station peut être troublée *directement* par des variations de la condition électrique (résistance intérieure et force électro-motrice) des deux piles E et e.

Dans les deux méthodes précédentes, la variation de la résistance intérieure de la pile de ligne ne peut être ressentie qu'*indirectement* par l'altération de la balance à l'autre station et la variation de la force électromotrice n'a pas d'effet du tout. De là résulte qu'une variation donnée se produisant dans l'une ou dans les deux piles doit troubler plus profondément la balance avec la *méthode de compensation* qu'avec les deux méthodes précédentes. L'on sait que même dans les piles dites constantes, en fonction, les conditions électriques varient très-sensiblement, surtout en ce qui concerne la résistance intérieure; ce défaut tranche donc la question au détriment de la méthode de compensation. Sous tous les autres rapports, cette méthode présente les mêmes défauts que la méthode différentielle et elle en a, en outre, quelques autres que vont faire ressortir les procédés d'investigation.

Expressions générales pour les deux fonctions « D » et « S ».

Pour obtenir les fonctions D et S, nous avons à développer les expressions générales pour les forces p, P et Q, soit pour la station I.

$$p' = A' m' - B' n'$$

expression dans laquelle A' et B' représentent les courants qui passent par les deux bobines a' et b', quand

2) Le Dr. Wilhelm Gintl, Directeur général des télégraphes autrichiens, est l'inventeur de cette méthode qui est la plus ancienne. C'est en 1853 qu'il fit les premières expériences sur une ligne entre Vienne et Prague (386 kilomètres).

11

DUPLEX TELEGRAPHY.

We have lately had occasion to record, in an incidental [w]ay, that a system of duplex telegraphy has been success[ful]ly introduced upon some of the lines between this country and India, and the success is of sufficient importance to require a somewhat more extended notice. In the original methods of telegraphy the signal is produced by a battery current, which is passed through the sending station, along the connecting wire, to the receiving station, and then through the earth, back to the battery from whence it came, so as to make a complete circuit. In the course of this circuit the current passes through the recording instrument at the sending station, as well as through that at the receiving station, so that the operator produces his signal upon his own instrument as well as upon that with which he wishes to communicate. It follows that the instrument at the sending station, being thus disturbed by the current which is passing through it, cannot, at the same time, be receiving a message from the other extremity of the line; and electricians have long been engaged in researches with a view to alter this condition of things, and to leave the instrument at the sending station unaffected, so that it may be able to receive messages and to record them.

The difficulties in the way of accomplishing this object were found to be much greater on long than on short lines, and very much greater on submarine cables than upon land lines of whatever length. The latter differ from the former by being more completely insulated; the submarine cables being surrounded by water which is in contact with the earth, and which brings them into direct relation with it. One effect of this relation is that the passage of the battery current along the wire produces an induced current around it, which delays the speed of the battery current, so that this, instead of travelling rapidly, as it does upon land, travels very slowly, and flows out of the wire in a way which has often been compared to the escape of a viscid liquid. For this and other reasons, the submarine lines require to be furnished with recording instruments of much greater delicacy than those which are used for land lines, and the former are, therefore, more liable to be disturbed. The principle on which efforts at the attainment of duplex telegraphy have been made is that if the original battery current is split into two equal parts, these may be conducted around the recording instruments by two different wires proceeding in opposite directions, and may then be conveyed along two different circuits; one half-current serving to excite the recording instrument at the distant station, the other half, after fulfilling its function of "balancing" the needle at the sending station, being simply wasted. The power of the second half-current to balance the recording instrument at the sending station—that is, exactly to counteract the signalling half-current—depends upon the two being precisely of the same strength; and this only happens when the two circuits which they respectively travel are precisely of the same resistance. If the circuit, say to the left, is of less resistance than that to the right, more electricity will flow to the left than to the right; the original battery current will thus be unequally divided, and the recording instrument will no longer be balanced—that is, it will no longer remain at rest while the divided current is passing. On land lines, formed by wires suspended in the air, the resistance of the signalling wire to the current is easily ascertained, and is easily imitated on the second or artificial circuit; but in submarine lines, on account of the induction already mentioned, there is not only the resistance to be taken into account, but also the returning capacity of the cable. In any given cable, each knot of length presents a certain resistance, and has also a certain returning capacity; but these two qualities do not bear the same proportion to each other in any two cables, and have to be separately tested in each. The second circuit, which for the land line need only be equal to the signalling wire in resistance, must for the cable be equal to it both in resistance and in capacity; and it has been found very difficult to fulfil both these requirements. It is not enough that the whole of the second circuit should be equal to the whole of the cable, but the resistance and the capacity must be distributed equally in both, and any portion of the second circuit must be equal to any corresponding portion of the cable.

Attempts have been made by Mr. Varley, Mr. Stearn, and others to overcome the difficulty by various combinations of condensers with resistance coils; the former to imitate the capacity, the latter the resistance, of the submarine cable itself. All these combinations seem to have failed from not being sufficiently uniform in their qualities; but Mr. J. Muirhead, Jr., has lately succeeded in obtaining the uniformity which was desired. He has formed his second circuit by sheets of paper prepared with paraffin, and having upon one side a strip of tinfoil, wound to and fro, to represent resistance, and through which the second current is conducted, and on the other side a sheet of tinfoil, to represent the gutta percha or other covering of the wire and to afford the capacity. Each sheet of paper may thus be made to represent precisely a given length of cable, having enough tinfoil on one side to furnish the resistance, and enough on the other to furnish the capacity. It follows that a sufficient number of such sheets would exactly represent the cable in every part of its length, and that the non-signalling half of the current would be precisely equal to and would be discharged under precisely the same conditions with the signalling half. For utilizing this invention two methods may be employed; the two halves of the current being either carried around the recording instrument in different directions, as already mentioned, or the two circuits being connected near their point of divergence by a Wheatstone bridge, on which the recording instrument is placed. Then, as long as the divided current flows evenly, one-half along the signalling wire to the recording instrument at the distant station, the other half along the artificial circuit, the equilibrium of the bridge between the two is not disturbed, and the instrument placed upon it is not affected. But as soon as the operator at the distant station, who has a precisely similar arrangement, sends a battery current into the signalling wire from his end of the line, this meets and opposes the half-current which is coming toward him. The flow through the signalling wire is thus interrupted, and, in consequence, the resistance of the two circuits being no longer equal, the balance of the first recording instrument is disturbed, and is disturbed to a degree which is regulated by the admission of the current from the other end. The result of this is that a single wire will convey signals simultaneously in two opposite directions, and that one wire will do the work for which two have previously been required.

On all marine lines this invention of Mr. Muirhead's is of the greatest possible importance, on account of the enormous expense of laying additional cables to meet increasing traffic; and also because, while it theoretically doubles the carrying capacity of each cable, it does still more than this in practice, by doing away with much loss of time in arranging about the precedence of outward and homeward messages, and about the repetition of those which were not perfectly intelligible at first. The new plan was first tried, on a working scale, on the line between Marseilles and Bona; but it has since been brought into operation from Marseilles to Malta, from Suez to Aden, and, lastly, from Aden to Bombay. On a very recent occasion, when there was a breakdown upon the Indo-European line, the duplex system rendered essential service, and maintained telegraphic communication which would otherwise have been most seriously interfered with. Mr. Muirhead's invention cannot fail to be highly profitable to the proprietors of submarine cables, and it will, we hope, before long, bring about a material reduction in the cost of messages from places beyond the seas.—*London Times*.

Good Work on the Duplex.

78

New York, *March* 30.

To the Editor of the Journal of the Telegraph:

On the 29th inst. there was transmitted from the Board of Trade Office in this city to Chicago on the duplex, between 10.35 A. M. and 2.10 P. M., 257 messages, being an average of about 72 messages per hour. There were received on the same wire during the same time 182 messages; making a total of 441 messages in 3 hours, 35 minutes. Very good work for a branch office.

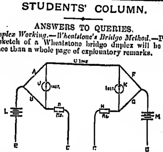
STUDENTS' COLUMN.

ANSWERS TO QUERIES.

3. *Duplex Working.—Wheatstone's Bridge Method.*—Perhaps a rough sketch of a Wheatstone bridge duplex will be of more assistance than a whole page of explanatory remarks.



Arms A and B equal say 100 ohms each; C and D equal 2000 ohms each. If L is sending to M no current will pass through Inst. I. Should Station M wish to send at the same time, the equilibrium of the current is disturbed, and signals recorded at I. Reverse the order, and signals will be recorded at M. Further and fuller particulars will be found in Culley's 6th edition, and Preece and Sivewright's text book.

4. *Joint Resistance.*—The rule for finding the joint resistance of two wires is to divide their product by their sum, thus—

$$\frac{75 \times 125}{75 + 125} = 41{\cdot}875 \text{ joint resistance.}$$

The two wires having a resistance of 75 and 125 are in proportion of 3 and 5. If, therefore, the 25 farads be divided into 8 parts, 5 parts, or 15·625, will go by the wire containing 75 ohms, and 3 parts, or 9·375 farads, by that with 125 ohms.

Wm. Dennett, Dover P.O.

Nov 78

Mr. J. B. Stearns has just succeeded in duplexing the Anglo-American Cable by his ordinary condenser system. The balance he has obtained, we understand, is absolutely complete, and the working of the siphon recorder (the instrument employed) is just as perfect as it was when single working was employed. Considering the marvellous sensitiveness of the siphon instrument this result is in the very highest degree satisfactory, and we congratulate Mr. Stearns on the success he has attained.

Duplex and Quadruplex Telegraphy in the States.—The progress of American land lines certainly compares favourably with that of England. We can boast of one quadruplex circuit. America has fifty-nine such circuits, comprising 16,157 miles of line; while it has also fifty-two duplex circuits, containing 14,580 miles of line, giving a grand total of 30,737 miles working duplex or quadruplex. July 78

Sieur's Duplex Telegraph.—The duplex system of M. Sieur, the apparatus for which is exhibited in the Telegraphic Annexe of the French Exhibition, is shortly to be adopted on the line between Paris and Rouen. It is distinct in principle from all other practical duplex systems, being based upon the use of a "distributor," or automatic current reverser, which divides the time of sending into a series of small and equal intervals, during which a succession of currents, alternately in opposite directions, are sent into the line. These currents are received separately on two polarised relays, corresponding respectively to the direction of the currents. This system equally admits of sending two messages simultaneously in the same direction, or in opposite directions. M. Sieur is said to have invented, also, a system of double and quadruple transmission, based, like the American systems, on the employment of currents of different intensity. Sept 78

[From *The Telegraphic Journal*.]

The Quadruplex System in England.

The quadruplex system of Messrs Edison and Prescott was introduced into this country in September, 1877. It has, therefore, been on trial here for a year.

Fears were from the first entertained that our variable climate would greatly interfere with the working of the system, and, at the outset a battery of 100 Fuller's Mercury-Bichromate Cells was used at each end of the wire; the supervisors being Mr. Gerrit Smith, the Assistant Electrician of the Western Union Company in London, and Mr. Hamilton, also of the electrical department of that company at the Liverpool end. When once fairly started, and in spite of variable and stormy autumnal weather, the operation proved eminently successful. Four distinct circuits were worked steadily on that wire for six or seven consecutive hours daily, and the number of ordinary messages per hour transmitted on the quadruplex was at that time surprising. As many as 213 ordinary despatches were sent and received within the sixty minutes—a total said to exceed the highest number ever heretofore attained by American telegraphists in the native land of the system. This result appeared to astonish Messrs. G. Smith and Hamilton, who, not unnaturally, had believed the famed manipulation of their telegraphic compatriots to be entirely unapproachable.

The quadruplex continued to behave satisfactorily after the return of the American electricians to the States, and may b. said to have since then exceeded ev. n the most sanguine expectations of its capabilities.

After having been in operation for some months to Liverpool, the apparatus was removed to Leeds, where a number of experiments have been made, and some improvements introduced that will materially enhance its value. The carrying power of the instrument, great as it is, can be increased about twenty-five per cent. by the Wheatstone automatic duplex system being used on the "double current" side of the apparatus. This has been effected between London and Leeds at a speed of fifty to sixty words per minute in each direction, without at all interfering with the ordinary duplex working on the "single current" side. Thus we may employ two independent and different systems, both duplexed, and transmitting between them a grand total of, say, 260 messages per hour, upon one wire two or three hundred miles long. By the introduction of this important English improvement, the capacity of the quadruplex, as we have said, has been augmented, and, besides, it has demonstrated the economy in wires that will result from the extension of the system. For instance, if "one side" be used as a duplex Wheatstone automatic circuit from London to a large centre, such as Manchester, the other section may be worked independently as an ordinary duplex circuit to, say, Carlisle. If a local line wire between Manchester and Carlisle be connected to the quadruplex apparatus, which would act as a translator or repeater on the "single current" side. A London-Manchester length would thus be economized.

We believe that the Post Office have decided to extend the quadruplex system immediately to several important telegraphic towns; in fact, the additional apparatus required for six or seven new sets are now nearly completed. Birmingham, Bristol, Southampton, Plymouth, and Jersey are spoken of as likely to receive the early benefit of these additional instruments.

Muirhead and Winter's Quadruplex.—This novel system of quadruplex is working very successfully on the trans-Indian line, between Madras and Bombay. It is a split battery system, and promises to be superior to Edison and Prescott's. We are obliged to reserve a full account of it until the patents are secured, but will do so then. The advantages claimed for it are (1) that considerable change in the resistance of the line do not disturb the balance; (2) that the receiving instruments do not require to be differentially wound, and (3) that there is no loss of current-power from the use of a Wheatstone Bridge. Feb. 79

An Octoplex Printing Telegraph.—Prof. Klinkerfues, the director of the Gottingen Observatory, has, it is said, taken out a patent for a new invention in telegraphy. The professor has discovered a method by which up to eight different messages may be sent simultaneously by the same wire, an apparatus at the receiving end printing the messages separately and all at the same time.

Mining & Sci. Press Nov 22 1879

Engineering, Dec 21, '83.

Kerite Telegraph Cable.

Kerite is the invention of an American manufacturer, Mr. A. G. Day, who was impelled by the increasing cost of india-rubber to seek a substitute for it as an insulating material for electric wires. The invention is patent, and the substances of which kerite is composed are not made public; but it is known that it is composed of various bodies. It may be combined with india-rubber, sulphur, and oxides of metals in the usual manner; renders the india-rubber more durable, while reducing the cost, and is applicable to the whole class of goods into the manufacture of which caoutchouc enters. At Mr. Day's factory at Seymour, Conn., the whole process of the manufacture of cable is carried on, except that of making the wire. The ingredients of the kerite are thoroughly mixed, put into boilers, and allowed to stand until ready for use. When hot the composition is of about the consistency of thick treacle; it is run into cakes, which, when cool, are kept separated by a thin layer of soapstone, in order to facilitate handling. Pure Para gum, cleansed by a process of Mr. Day's invention, is then thoroughly mixed with the kerite by the usual grinding operation, and the whole carefully strained. It is afterwards cut into strips about an inch square, and fed into a machine, which covers it on to the wire as the latter passes through. The wire is then coiled in layers in large pans, fine soapstone dust being used to prevent adhesion, and is vulcanised. The coils are afterwards rewound upon "testing reels," and submerged in water for forty-eight hours. The wire is most carefully tested while in the bath, and the process is then complete. Wire for single lines is wound and despatched at this point, while that for cables is wound up for the cable-making machines. Submarine cables have a coating of prepared tape over each strand, they are then surrounded with an envelope of jute fibre, and, lastly, enclosed in an armour of the best "B. B." galvanised iron wire.

55

...EGRAPHIC APPARATUS FOR DUPLEX TRANSMISSION.

BY S. W. DE SUSSEX.

...isation of the Poles of a Magnet.—If a permanent magnet ...he form of a horse shoe, has its arms prolonged by pieces ...iron, the magnetic poles of the primitive magnet will be transferred to the extremity of the soft iron, that is to say, the south pole to *a*, and the north pole to *b* (fig. 1). Now direct a current around the soft iron bars B, by means of coils. The current will act upon the bars of soft iron fixed to the permanent magnet. If, at the moment when the current is passing through, we place a magnetic needle near the extremity *b* of the magnet A, prolonged by the soft iron bars B, we shall see this bar deviate considerably from its original position, indicated by fig. 2. And, if the current be of sufficient intensity, the needle will be reversed, its pole *b'* will turn towards *b*, thus indicating to us that at the extremity of the soft iron extension of the magnet A, and at *b'*, we have produced a southern pole, that is to say, at this extreme point, a complete reversal of the magnetism of the primitive magnet A. In other words, the two arms become by the passage of the current two electro-magnets, the communication of which, with the permanent magnet A, nevertheless, does not modify the poles of the magnet A. The same thing takes place in an opposite direction with the extension of the other pole, since we have taken for granted the simultaneous passage of the current in the two coils.

A magnetized Armature of Steel or Soft Iron is repelled from the Poles of a Magnet.—Let us place beneath the arms, and at a very short distance from them, an armature of soft iron, or of magnetized steel (fig. 2). At the moment of the passage of the current this armature is repelled. In fact, if the armature is of magnetized steel, and such that its north pole lies under the south pole, and its south pole under the north pole of the permanent magnet A, this armature, at the moment of the passage of the current, will be repelled by the prolonged poles of the magnet A, which, as we have shown, become of the same kind as those of the extremities of the armature of magnetized steel. If, on the contrary, this armature is of soft iron, it becomes, in fact, magnetized by the induction of the permanent magnet A, and its poles are similar to those in the case of a magnetized armature; thus, on the passage of the current, the same phenomenon of repulsion will be observed.

Application to the Construction of Telegraphic Receivers.—Let us remove the call-spring of a telegraphic receiver, and replace it by a permanent magnet prolonged by arms of soft iron surrounded by coils, as indicated in figure 2. We have fixed these coils in such a manner as that the circulating current shall polarise the prolonged poles of the permanent magnet A, whilst at the same time determining, in an electro-magnet placed below the armature, a magnetism of the same kind as that of the permanent magnet A. It is clear that we shall have obtained an attraction of the armature by the lower electro-magnet thus formed, at the same time having determined a downward repulsion of this armature, a repulsion due to the formation of the upper electro-magnets. This phenomenon will continue till the moment when, the interruption of the current withdrawing all magnetic action from the various electro-magnets, the permanent magnet A alone becomes active, and, being extended then to the extremity of the arms which prolong it, brings back the armature to its original position. There is here a differential action, and the equilibrium being well established by the adjustment of an instrument thus constructed, will allow us to work it with a very much reduced electro-motive force; since, whatever this force may be, there will always be attraction on the one hand and repulsion on the other.

Special Application of the Receivers.—It is in accordance with these observations and these data that we have constructed an instrument which can be adapted to ordinary telegraphic receivers. Here, for instance, is a description of this instrument applied to the Morse system. In the ordinary Morse instrument the point, by means of which the whole of the signals are reproduced on the paper which is unwound by the clockwork, is supported by a lever, which at its other end supports the armature of an electric magnet. This armature is kept at a distance from the electro-magnet by means of a small spring. When a current from the line passes into the coils of the electro-magnet the armature is attracted. On the other hand, it follows from our first explanation that if, instead of keeping the armature at a distance from the poles of the electro-magnet by means of a spring, we keep it at a distance by the permanent magnet A, we shall have a magnetic spring in place of a mechanical spring. But at the moment of the passage of the current this spring will be repellent, whilst below we shall have excited by the lower electro-magnet an ...ttractive force. The armature will thus be doubly attracted, and will lower itself, and rise again only on the interruption of the current.

Explanation of Fig. 3, showing the whole of a Morse Receiver furnished with the Apparatus.—Fig. 3 shows in principle the construction of our apparatus applied to a Morse receiver. A is the permanent magnet; R the regulator, of soft iron, working by means of a rack, in order to allow the force of the permanent magnet A to be increased or diminished at will. There is a screw which by means of a brass cross-piece is joined on to the permanent magnet A. The end of this screw presses against a support, and the magnet being fixed *à charnières*, we can, by means of this screw, at will cause the prolonged poles of the permanent magnet to approach the armature or retire from it. This screw, again, is furnished with a counter stop-screw, so that the working of the apparatus may not gradually cause the upper coils to slip down.

We dwell upon these details because the adjustment of the apparatus depends on this regulator and this screw. G is a copper cross-piece fixed on to the body of the Morse, and supporting the magnet and the two upper coils. T is a bar of soft iron joining the cores of the electro-magnet. P is the soft iron, or magnetised armature.

a. The extended southern pole of the permanent magnet A. *b*. Extended northern pole of the permanent magnet A. *a'*. Southern pole of the lower electro-magnet. *b'*. Northern pole of the lower electro-magnet. M. Case of the Morse.

Before going any further we will mention some experiments made with our apparatus:—

Correct Transmission through 30.000 Ohms.—We have succeeded in obtaining signals absolutely correct, through a resistance of 20,000 ohms, by making use of a rheostat belonging to Messrs. Latimer-Clark, Muirhead, and Co., of London. The number of cells employed was twenty-five Leclanchés, of seven centimètres in height. Sensitizing the apparatus by a careful adjustment, we succeeded in getting correct signals through 30,000 ohms. Another experiment was to make the apparatus work through a resistance of 1,000 ohms, with one small Leclanché cell. These experiments were made with the object of proving the sensitiveness of the apparatus.

Transmission through a Non-Insulated Wire.—A rather curious experiment was made at the Brussels Zoological Gardens, before fully competent persons. A bare copper wire of one-and-a-quarter millimètres in diameter had been unwound upon the ground, in the grass, the shrubs, &c., for the distance of a kilomètre. The earth-plates were of copper, laid horizontally, and measuring forty-nine square décimètres. The battery used was a small Leclanché of ten cells. The signals were transmitted very regularly, and we think that no more conclusive proof can be given of the sensitiveness of the apparatus and the small electro-motive force which it requires. It should be observed that, the day before this experiment was made, and the whole time it was going on, a fine rain was falling, such as is always detrimental to electric telegraphy. From the series of facts which we have just enumerated we gather clearly that the apparatus works at much greater distances than the various receivers with springs at present in use, and that it has the advantage of needing a much smaller electro-motive force than any of them.

Duplex working without Condensers.—But the advantages we have just mentioned are secondary. The apparatus possesses others far more important, which we will proceed to analyse, and the demonstration of which will form a sequel to the description of our apparatus. The first of these advantages is that it allows not only simple transmission with reduced electro-motive force, but also duplex working without condensers. Of course, we are not speaking here of submarine lines, or of aerial lines of too great length. Our experiments seem to impose upon us a limit of from 400 to 500 kilomètres, according to the lines.

Automatic Control of Messages.—Another no less important advantage is the power of automatically controlling messages. For a commutator added at the two stations enables us to transform the lever of the receiver into a manipulator, so that the sender can follow with absolute certainty the reception of the message by his correspondent, which is undoubtedly the most complete control to be possibly obtained.

Rheostat.—The apparatus is furnished with a rheostat, but this rheostat, placed in a pigeon-hole drawer under the wooden pedestal of the Morse, is composed of only three coils of very fine wire. Each of these coils is of a different resisting power; they are marked respectively—*very dry weather*, *ordinary weather*, and *thaw* or *bad weather*. This set of coils, or rather this rheostat thus composed, is arranged according to a proportion which we shall speak of shortly, and this proportion is fixed in accordance with a law based on the resistance, or part of the resistance, of the coils of the electro-magnets and of the line. By this method of construction of the rheostat, and by the differential adjustment of the apparatus, we have succeeded in

The Quadruplex System in England.

The quadruplex system of Messrs. Edison and Prescott was introduced into this country in September, 1877. It has, therefore, been on trial here for a year.

Fears were from the first entertained that our variable climate would greatly interfere with the working of the system, and, at the outset a battery of 100 Fuller's Mercury-Bichromate Cells was used at each end of the wire; the supervisors being Mr. Gerritt Smith, the Assistant Electrician of the Western Union Company in London, and Mr. Hamilton, also of the electrical department of that company at the Liverpool end. When once fairly started, and in spite of variable and stormy autumnal weather, the operation proved eminently successful. Four distinct circuits were worked steadily on that wire for six or seven consecutive hours daily, and the number of ordinary messages per hour transmitted on the quadruplex was at that time surprising. As many as 213 ordinary despatches were sent and received within the sixty minutes—a total said to exceed the highest number ever heretofore attained by American telegraphists in the native land of the system. This result appeared to astonish Messrs. G. Smith and Hamilton, who, not unnaturally, had believed the famed manipulation of their telegraphic compatriots to be entirely unapproachable.

The quadruplex continued to behave satisfactorily after the return of the American electricians to the States, and may be said to have since then exceeded even the most sanguine expectations of its capabilities.

After having been in operation for some months to Liverpool, the apparatus was removed to Leeds, where a number of experiments have been made, and some improvements introduced that will materially enhance its value. The carrying power of the instrument, great as it is, can be increased about twenty-five per cent. by the Wheatstone automatic duplex system being used on the "double current" side of the apparatus. This has been effected between London and Leeds at a speed of fifty to sixty words per minute in each direction, without at all interfering with the ordinary duplex working on the "single current" side. Thus we may employ two independent and different systems, both duplexed, and transmitting between them a grand total of, say, 260 messages per hour, upon one wire two or three hundred miles long. By the introduction of this important English improvement, the capacity of the quadruplex, as we have said, has been augmented, and, besides, it has demonstrated the economy in wires that will result from the extension of the system. For instance, if "one side" be used as a duplex Wheatstone automatic circuit from London to a large centre, such as Manchester, the other section may be worked independently as an ordinary duplex circuit to, say, Carlisle, if a local line wire between Manchester and Carlisle be connected to the quadruplex apparatus, which would act as a translator or repeater on the "single current" side. A London-Manchester length would thus be economized.

We believe that the Post Office have decided to extend the quadruplex system immediately to several important telegraphic towns; in fact, the additional apparatus required for six or seven new sets are now nearly completed. Birmingham, Bristol, Southampton, Plymouth, and Jersey are spoken of as likely to receive the early benefit of these additional instruments.

Muirhead and Winter's Quadruplex.—This novel system of quadruplex is working very successfully on the trans-Indian line, between Madras and Bombay. It is a split battery system, and promises to be superior to Edison and Prescott's. We are obliged to reserve a full account of it until the patents are secured, but will do so then. The advantages claimed for it are (1) that considerable change in the resistance of the line do not disturb the balance; (2) that the receiving instruments do not require to be differentially wound, and (3) that there is no loss of current-power from the use of a Wheatstone Bridge. Feb 79

An Octoplex Printing Telegraph.—Prof. Klinkerfues, the director of the Gottingen Observatory, has, it is said, taken out a patent for a new invention in telegraphy. The professor has discovered a method by which up to eight different messages may be sent simultaneously by the same wire, an apparatus at the receiving end printing the messages separately and all at the same time.

Engineering Dec 24, 1883.

Kerite Telegraph Cable.

Kerite is the invention of an American manufacturer, Mr. A. G. Day, who was impelled by the increasing cost of india-rubber to seek a substitute for it as an insulating material for electric wires. The invention is patent, and the substances of which kerite is composed are not made public; but it is known that it is composed of various bodies. It may be combined with india-rubber, sulphur, and oxides of metals in the usual manner; renders the india-rubber more durable, while reducing the cost, and is applicable to the whole class of goods into the manufacture of which caoutchouc enters. At Mr. Day's factory at Seymour, Conn., the whole process of the manufacture of cable is carried on, except that of making the wire. The ingredients of the kerite are thoroughly mixed, put into boilers, and allowed to stand until ready for use. When hot the composition is of about the consistency of thick treacle; it is run into cakes, which, when cool, are kept separated by a thin layer of soapstone, in order to facilitate handling. Pure Para gum, cleansed by a process of Mr. Day's invention, is then thoroughly mixed with the kerite by the usual grinding operation, and the whole carefully strained. It is afterwards cut into strips about an inch square, and fed into a machine, which covers it on to the wire as the latter passes through. The wire is then coiled in layers in large pans, fine soapstone dust being used to prevent adhesion, and is vulcanised. The coils are afterwards rewound upon "testing reels," and submerged in water for forty-eight hours. The wire is most carefully tested while in the bath, and the process is then complete. Wire for single lines is wound and despatched at this point, while that for cables is wound up for the cable-making machines. Submarine cables have a coating of prepared tape over each strand, they are then surrounded with an envelope of jute fibre, and, lastly, enclosed in an armour of the best "B. B." galvanised iron wire.

EGRAPHIC APPARATUS FOR DUPLEX TRANSMISSION.

BY S. W. DE SUSSEX.

…isation of the Poles of a Magnet.—If a permanent magnet …he form of a horse shoe, has its arms prolonged by pieces …iron, the magnetic poles of the primitive magnet will be transferred to the extremity of the soft iron, that is to say, the south pole to *a*, and the north pole to *b* (fig. 1). Now direct a current around the soft iron bars B, by means of coils. The current will act upon the bars of soft iron fixed to the permanent magnet. If, at the moment when the current is passing through, we place a magnetic needle near the extremity *b* of the magnet A, prolonged by the soft iron bars B, we shall see this bar deviate considerably from its original position, indicated by fig. 2. And, if the current be of sufficient intensity, the needle will be reversed, its pole *b'* will turn towards *b*, thus indicating to us that at the extremity of the soft iron extension of the magnet A, and at *b'*, we have produced a southern pole, that is to say, at this extreme point, a complete reversal of the magnetism of the primitive magnet A. In other words, the two arms become by the passage of the current two electro-magnets, the communication of which, with the permanent magnet A, nevertheless, does not modify the poles of the magnet A. The same thing takes place in an opposite direction with the extension of the other pole, since we have taken for granted the simultaneous passage of the current in the two coils.

A magnetized Armature of Steel or Soft Iron is repelled from the Poles of a Magnet.—Let us place beneath the arms, and at a very short distance from them, an armature of soft iron, or of magnetized steel (fig. 2). At the moment of the passage of the current this armature is repelled. In fact, if the armature is of magnetized steel, and such that its north pole lies under the south pole, and its south pole under the north pole of the permanent magnet A, this armature, at the moment of the passage of the current, will be repelled by the prolonged poles of the magnet A, which, as we have shown, become of the same kind as those of the extremities of the armature of magnetized steel. If, on the contrary, this armature is of soft iron, it becomes, in fact, magnetized by the induction of the permanent magnet A, and its poles are similar to those in the case of a magnetized armature; thus, on the passage of the current, the same phenomenon of repulsion will be observed.

Application to the Construction of Telegraphic Receivers.—Let us remove the call-spring of a telegraphic receiver, and replace it by a permanent magnet prolonged by arms of soft iron surrounded by coils, as indicated in figure 2. We have fixed these coils in such a manner so that the circulating current shall polarise the prolonged poles of the permanent magnet A, whilst at the same time determining, in an electro-magnet placed below the armature, a magnetism of the same kind as that of the permanent magnet A. It is clear that we shall have obtained an attraction of the armature by the lower electro-magnet thus formed, at the same time having determined a downward repulsion of this armature, a repulsion due to the formation of the upper electro-magnets. This phenomenon will continue till the moment when, the interruption of the current withdrawing all magnetic action from the various electro-magnets, the permanent magnet A alone becomes active, and, being extended then to the extremity of the arms which prolong it, brings back the armature to its original position. There is here a differential action, and the equilibrium being well established by the adjustment of an instrument thus constructed, will allow us to work it with a very much reduced electro-motive force; since, whatever this force may be, there will always be attraction on the one hand and repulsion on the other.

Special Application of the Receivers.—It is in accordance with these observations and these data that we have constructed an instrument which can be adapted to ordinary telegraphic receivers. Here, for instance, is a description of this instrument applied to the Morse system. In the ordinary Morse instrument the point, by means of which the whole of the signals are reproduced on the paper which is unwound by the clockwork, is supported by a lever, which at its other end supports the armature of an electric magnet. This armature is kept at a distance from the electro-magnet by means of a small spring. When a current from the line passes into the coils of the electro-magnet the armature is attracted. On the other hand, it follows from our first explanation that if, instead of keeping the armature at a distance from the poles of the electro-magnet by means of a spring, we keep it at a distance by the permanent magnet A, we shall have a magnetic spring in place of a mechanical spring. But at the moment of the passage of the current this spring will be repellent, whilst below we shall have excited by the lower electro-magnet an [illegible] force. The armature will thus be doubly attracted, and will lower itself, and rise again only on the interruption of the current.

Explanation of Fig. 3, showing the whole of a Morse [illegible] furnished with the Apparatus.—Fig. 3 shows in principle the construction of our apparatus applied to a Morse receiver. A is the permanent magnet; R the regulator, of soft iron, working by means of a rack, in order to allow the force of the permanent magnet A to be increased or diminished at will. There is a screw which by means of a brass cross-piece is joined on to the permanent magnet A. The end of this screw presses against a support, and the magnet being fixed *à charnières*, we can, by means of this screw, at will cause the prolonged poles of the permanent magnet to approach the armature or retire from it. This screw, again, is furnished with a counter stop-screw, so that the working of the apparatus may not gradually cause the upper coils to slip down.

We dwell upon these details because the adjustment of the apparatus depends on this regulator and this screw. G is a copper cross-piece fixed on to the body of the Morse, and supporting the magnet and the two upper coils. T is a bar of soft iron joining the cores of the electro-magnet. P is the soft iron, or magnetised armature.

a. The extended southern pole of the permanent magnet A. *b*. Extended northern pole of the permanent magnet A. *a'*. Southern pole of the lower electro-magnet. *b'*. Northern pole of the lower electro-magnet. M. Case of the Morse.

Before going any farther we will mention some experiments made with our apparatus:—

Correct Transmission through 30,000 Ohms.—We have succeeded in obtaining signals absolutely correct, through a resistance of 20,000 ohms, by making use of a rheostat belonging to Messrs. Latimer Clark, Muirhead, and Co., of London. The number of cells employed was twenty-five Leclanchés, of seven centimètres in height. Sensitizing the apparatus by a careful adjustment, we succeeded in getting correct signals through 30,000 ohms. Another experiment was to make the apparatus work through a resistance of 1,000 ohms, with one small Leclanché cell. These experiments were made with the object of proving the sensitiveness of the apparatus.

Transmission through a Non-Insulated Wire.—A rather curious experiment was made at the Brussels Zoological Gardens, before fully competent persons. A bare copper wire of one-and-a-quarter millimètres in diameter had been unwound upon the ground, in the grass, the shrubs, &c., for the distance of a kilomètre. The earth-plates were of copper, laid horizontally, and measuring forty-nine square décimètres. The battery used was a small Leclanché of ten cells. The signals were transmitted very regularly, and we think that no more conclusive proof can be given of the sensitiveness of the apparatus and the small electro-motive force which it requires. It should be observed that, the day before this experiment was made, and the whole time it was going on, a fine rain was falling, such as is always detrimental to electric telegraphy. From the series of facts which we have just enumerated we gather clearly that the apparatus works at much greater distances than the various receivers with springs at present in use, and that it has the advantage of needing a much smaller electro-motive force than any of them.

Duplex working without Condensers.—But the advantages we have just mentioned are secondary. The apparatus possesses others far more important, which we will proceed to analyse, and the demonstration of which will form a sequel to the description of our apparatus. The first of these advantages is that it allows not only simple transmission with reduced electro-motive force, but also duplex working without condensers. Of course, we are not speaking here of submarine lines, or of aerial lines of too great length. Our experiments seem to impose upon us a limit of from 400 to 500 kilomètres, according to the lines.

Automatic Control of Messages.—Another no less important advantage is the power of automatically controlling messages. For a commutator added at the two stations enables us to transform the lever of the receiver into a manipulator, so that the sender can follow with absolute certainty the reception of the message by his correspondent, which is undoubtedly the most complete control to be possibly obtained.

Rheostat.—The apparatus is furnished with a rheostat, but this rheostat, placed in a pigeon-hole drawer under the wooden pedestal of the Morse, is composed of only three coils of very fine wire. Each of these coils is of a different resisting power; they are marked respectively—*very dry weather*, *ordinary weather*, and *thaw* or *bad weather*. This set of coils, or rather this rheostat thus composed, is arranged according to a proportion which we shall speak of shortly, and this proportion is fixed in accordance with a law based on the resistance, or part of the resistance, of the coils of the electro-magnets and of the line. By this method of construction of the rheostat, and by the differential adjustment of the apparatus, we have succeeded in

Engineer, July 14, 1882.

NEW METHOD OF WORKING LONG TELEGRAPHS.

In working long telegraph circuits where an automatic translator or repeater cannot be employed between two sections for the purpose of forwarding a message from one section to the other, it is customary to employ a clerk or operator to receive and write down the message arriving on one section and then pass it to another clerk who transmits it over the next section. In this process a great deal of valuable time is wasted by the writing of the message at the intermediate station, and a new system of personal translation has been introduced by Sir James Anderson and Mr. Benjamin Smith, of the Eastern Telegraph Company, to avoid this delay and facilitate the despatch of traffic by transmitting it direct while it is being received. Briefly described, it consists in causing the clerk who receives the message from one section to send it at the same time over the next section; so that while he is reading the message from the receiver as it comes he is also re-transmitting it further on its way, thus playing the part of a human relay or repeater as distinguished from an automatic relay. The new system, which has been already adopted on the submarine lines of the Eastern, Eastern Extension, and South African Telegraph Companies, has many advantages over the old system of working. These are in point of despatch of traffic, accuracy of transmission, and economy of labour and apparatus. First, with regard to despatch of business, the time at present lost in writing down the message received by one clerk, say from station A, and passing it to another clerk to be transmitted over the next section to station C, is entirely saved, for the clerk who receives it from station A is all the while transmitting it to station C himself, and thus the message gets to station C in the same time that by the ordinary system it takes to reach station B, thus traversing two sections of the line in the same time as is ordinarily occupied in traversing one. Greater accuracy of sending is insured by the fact of there being no intermediate copying of the message; and the clerk can give his whole attention to the reading and re-transmitting of the message. Further, by means of this direct personal translation, one clerk suffices to do the work of two in working lines by the simplex method; for instead of having one clerk to receive and another to transmit, the same clerk both receives and transmits simultaneously. Thus the translating station can be manned by half the usual number of operators. Where the duplex method of working is employed there is a still greater saving of labour, for ordinarily six clerks are necessary to work two duplex circuits, namely, three to each section, one to receive, one to transmit, and a third to look up errors for correction, so that the others may continue at their proper duties uninterruptedly. By the new system of Messrs. Anderson and Smith these six men are replaced by two, each receiving from one section and transmitting to the next without delay. A very much smaller staff is therefore necessary at intermediate stations, and a saving is effected in the expenses of the *personnel*, as well as in stationery and apparatus.

58

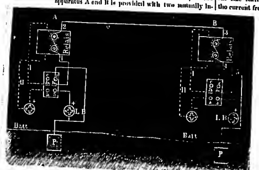
Transmitting Telegrams Simultaneously in Opposite Directions over a Single Wire.

The transmission of telegraphic signals simultaneously over the same wire in opposite directions was for a long time supposed to be utterly impossible. According to the old theory of electricity it was considered as a subtle imponderable fluid or force, and the conclusion was unavoidable that if two such fluids or forces of equal intensity meet in opposite directions they neutralize or annul one another. Some advanced minds, however, began to see a similarity in the mode of the propagation of sound, light, and electricity, and therefore suspected that the so-called electric current passing through a wire was nothing but a wave motion transmitted from atom to atom, with a velocity intermediate between that of sound and light, and that it would be subject to the same laws. It is known that sonorous waves are transmitted in long tubes in contrary directions without the least interference, that the different rays of light or luminous waves coming from the stars, and in fact from every luminous or illuminated object, intercross in an infinite number of ways and never interfere, and finally that the electric currents of thousands of telegraph batteries come back to the station from which they are sent, through the earth as their common conductor, without ever manifesting any trace of being influenced one by the other.

Besides the question of the possibility of conducting simultaneously several currents in the same or opposite directions over one single wire, there is in practical telegraphy still another difficulty to be overcome. As well in the Morse system as the printing and chemical telegraphs, an arrangement has been adopted by which every time a dispatch is transmitted, the recording instrument of the transmitting office is disconnected from the line, and only the instrument of the receiving office is kept in the circuit. If we wish to transmit and receive telegrams over the same line, at the same time, this arrangement must be abandoned, and the receiving instruments of both stations must continually be kept in the line, so that each may be ready at any moment to receive a dispatch from the other station. If this were done without further precautions, the current of the transmitting station would affect also its own receiving instrument, and it would record its own dispatches at the same time with those received from the other station, which would of course result in the most fatal confusion.

The problem to be solved is therefore this: The receiving instruments or relays must at both stations be in permanent connection with the line, without being affected by the current of their own battery when messages are sent out.

This problem was first solved by the director of the Austrian telegraphs, Dr. Gintl. His arrangement is represented in the annexed figure. Each relay of the apparatus A and B is provided with two mutually independent coils, of which the interior one as usual is connected with the line and its battery; the exterior coil however, consisting of thicker wire, is connected with a compensating battery, in such a way however that the batteries, when the current is closed, throws a current around the electro-magnet in opposite directions, and so equal that they neutralize one another in their magnetic influence and do not affect the iron core at all.



DUPLEX SYSTEM OF TELEGRAPHING.

In order to accomplish this simultaneous closing and opening of the circuit for both batteries, a double key, over $a\,a'$, has been introduced, consisting of two single levers mutually isolated one from the other, but in its fore part connected by an isolated cross-piece. The double key has one single knob, by which both levers are simultaneously depressed and brought in contact at the same instant with the points $a\,a'$ underneath. In the state of rest these levers, which have their turning point or axis and connection in $b\,b'$, (just above $a\,a'$,) are in contact with the points $c\,c'$. The key at the right side, as is customary in the Morse system, is connected with the line battery L B, the relay, and the wire, as well as with the earth. The key at the left, on the contrary, is connected with the compensating battery and the exterior relay coil.

Now if at the station A the double key is depressed, the line battery L B and compensation battery are closed at the same time, the current of the first goes from + along a' b' and 1, through the inside coil of the relay through 2, over the line to station B, and here by 3 through the relay over 4, b', c', 5, ground connection P', subterranean conduction to P' of station A, and to the — pole of its line battery L B. At the same time the current of the compensation battery at the left goes from the + pole over a, b, 1, through the exterior coil of the electro-magnet and II to the — pole of the battery. The relay A is therefore influenced by two currents in opposite directions, while the relay B is only affected by the current of the line battery of station A.

It is easy to arrange the strength of the batteries and the length of coils in such a way that the effect of the two opposite currents on the relay will be perfectly neutral. Notwithstanding the relay of both stations is in the circuit, that of the transmitting station A is not affected, while the compensation battery here neutralizes the action of the line battery. The latter sends its current undisturbed to the receiving station B, when it magnetizes the relay, and so sets the writing apparatus in operation.

If now at station B the double key is depressed at the same time as at station A, then the current of the line battery goes here also (the same as in A) through the inner relay coil and the line wire to A, at the same time however the current of the compensating battery goes through the outer coil of the relay, and these two currents neutralize one another in the relay of station B; wherefore this is only affected by the current of the line battery coming from A, in the same way as the current from the line battery at B acts on the relay at A, therefore in both stations the instruments are recording the messages of the opposite station at the same time, and not their own.

It must be remarked however that when in A and B the key is depressed at the same instant, the current of the line battery in A takes another course in B than is the case when the key in B is not depressed. In the latter case the line current coming from A passes through 3, the inner relay coil, 4, b', c', 5, P', earth; in the former case (when the key in B is depressed) this current goes from 3 through the inner relay coil, 4, b', a', and through the line battery to the earth. It is the same in station A in regard to the currents coming from the line battery in B.

The practical tests with this arrangement have shown that the neutralization of the relays at the transmitting offices was the only condition to be satisfied, and that the opposite currents in the line of telegraph wire itself did not interfere or destroy each other, but crossed one another like two waves of sound, which is a strong argument against the old doctrine of electric fluid, and in favor of the modern theory that it is a mode of motion in ponderable matter, of a different nature however as in the case with heat, of which the mechanical nature may now be considered as one of the best established principles in the field of physics.

59

Duplexing the Atlantic Cable.

The simultaneous transmission of two telegraphic messages in opposite directions upon one wire, now known by the name of duplex telegraphy, dates back from the year 1853. In that year Dr. Gintl, the director of state telegraphs in Austria, described a method by which this feat could be accomplished, and in July of the same year the method suggested by Gintl was tried between Prague and Vienna. An improvement on this method was suggested by a German electrician, Frischen, by Messrs. Siemens and Halske, of Berlin, and other workers at this subject. Nevertheless, owing to practical difficulties, the experiments were little more than interesting additions to our knowledge. So little hope, indeed, was there of the practical realization of this important matter that, in a standard work on telegraphy, published in 1867, after describing the early methods of duplex telegraphy, the author remarks: "Systems of telegraphing in opposite directions, and of telegraphing in the same direction more than one message at a time, must be looked upon as little more than feats in 'intellectual gymnastics,' very beautiful in their way, but quite useless in a practical point of view." Such assertions should teach all scientific writers the lesson of "hoping all things not impossible, believing all things not improbable," an attitude of mind which, Sir John Herschel remarks, should always characterize the natural philosopher, and which, in the present day, is certainly the safest one. Within six years of the publication of the foregoing statement duplex telegraphy was not only largely employed in actual telegraphy, but its use on certain busy lines became absolutely indispensable. The change from theoretical to practical success is due to an American, Mr. J. B. Stearns, who, in 1872, succeeded in overcoming the main obstacle in duplex telegraphy, namely, what is known as the static discharge from the line. This Stearns accomplished by using a "condenser;" and further, he developed a system of "duplexing" the line similar to the principle of the Wheatstone bridge.

More or less successful attempts were afterwards made to duplex submarine cables, and in the early part of 1877 Mr. J. Muirhead succeeded in duplexing the cables of the Eastern Telegraph Company by his artificial condensers. But we believe that his success was only partial. Subsequently Mr. Muirhead has been at work duplexing the Direct United States Cable, with some prospect of success, and lately Stearns, who may be called the father of duplex telegraphy, has actually achieved the great feat of perfectly duplexing

[DECEMBER 21, 1878.

the Anglo-American cable. In a message received by Mr. W. H. Preece, Mr. Stearns says, "I managed to get some specimens for you this morning, though we had no time to make the balance especially perfect for the purpose."

All the messages now sent across the Atlantic are automatically registered by means of Sir W. Thomson's delicate and beautiful siphon recorder, which spirts out little jets of ink in a fine stream on a moving ribbon of paper. When no current passes the ink marks form a straight line, but a current causes this line to deviate to the right or left, according to the direction of current. Hence the ordinary right and left strokes of a needle instrument, or the long and short dashes of a Morse, are indicated by marks above and below the middle line.

The essence of duplex telegraphy is to obtain an electrical balance round on the line, such that the sending instrument is not affected by currents circulating round it coming from the sending end, but only by currents received from the opposite end, and *vice versa*. Hence, if the balance be once obtained, double transmission is possible. This balance Stearns has succeeded in obtaining by the use of his system as applied to land lines, and without the aid of the additional arrangements of artificial condensers used by Dr. Muirhead. —*Nature.*

Duplex Telegraphy.—Mr. Muirhead has recently successfully applied his duplex system of working telegraph lines to the cable from Madras to Penang, a length of about 1,300 miles. This extension of the system makes a total of about 10,000 miles of cable worked upon Mr. Muirhead's system, and we understand that, so far, it is the only successful method whereby long submarine cables are practically worked on the duplex principle. The Eastern Telegraph Company have for several years employed this system for working the traffic on all their trunk lines, and the latest extension, above referred to, carries the working as far east as Penang. Duplex telegraphy consists in a method of sending two messages on the same wire at the same time in opposite directions, and Mr. Muirhead's system was fully described in the *Times* about a year since.

Jan 79

MR. EDISON. — This inventor filed his bill in the Supreme Court of the District of Columbia, some days ago, against the Western Union Telegraph Company for an injunction to restrain infringement of patent for improvement in duplex telegraph, to establish title, &c. This is another remedy for an injury which has been complained of by Edison in other suits. It will be heard early next summer.

The Canadian Elec. News, Jan 1/81

A SINGLE POLE QUADRUPLEX. Jan 1/81

We have the pleasure to place before our readers a description of a Single Pole Quadruplex, which has just been invented by Superintendent B. B. Toye, of the Great North Western Telegraph Company's service at Toronto. We understand the patents have been applied for, as we are confident from the serviceable appearance of the innovation, that this new Canadian invention will be adopted everywhere in America and Europe.

We think the arrangement of Arm X a very pretty one, where it cuts out a magnet, when it is required to be cut out, and cuts it in again, when it is necessary to be in, and both by *a stroke in the same direction.*

The apparatus works remarkably well on a short line; and will, no doubt, do all that is anticipated, when introduced on a main business circuit.

We understand Mr. Toye has given this invention most of his spare time during the past six months, overcoming one difficulty after another, and in many cases "overcoming a difficulty" means introducing another, in another place. Thus it seems the main parts of this new invention are nearly as simple as a Repeater. We are pleased that a Canadian gentleman should be the first to invent this improvement, and we wish him all the success he merits.

STEARNS' SUBMARINE CABLE DUPLEX SYSTEM.

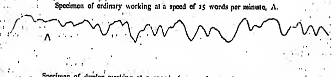
THERE can now be no doubt that submarine duplex telegraphy has fairly passed the experimental stage and is a practical success even as regards long cables. The difficulties which stood in the way of duplexing the long ocean cables seemed almost unsurmountable, and the feat was judged by many to be impossible. The success which has attended the labours of Messrs. Muirhead and Stearns, has practically set the matter at rest, and it is practically demonstrated that the longest cable ever likely to be laid can be duplexed. Very little is at present known of the details of the methods employed for effecting the end in view, in consequence of the question of the patent rights involved not having been settled; but we hope soon to make them clear.

As is well known, Mr. Stearns has lately turned his attention to the subject of duplexing the Atlantic cables, and has had complete success. We are able, through the kindness of Mr. Stearns, to reproduce some specimens of the records very recently obtained on the 1871 Atlantic cable duplexed by his system. The difficulty of preserving a balance with such a sensitive instrument as the Siphon Recorder must be evident, and the fact that the cable has now been working for more than two months, speaks well for the system.

The speed which has been obtained experimentally is as high as 50 words per minute, that is 25 words each way. This latter is as great a speed as can be obtained when working in the ordinary way.

The following fac-simile copies of the Recorder slip will shew that the signals are as perfect as can be wished:—

Specimen of ordinary working at a speed of 25 words per minute, A.



Specimen of duplex working at a speed of 25 words per minute each way, B.

MULTIPLE TELEGRAPHY.

THE following is an abstract of a lecture at the Royal Institution recently delivered by Mr. W. H. Preece. In commencing his lecture Mr. Preece said:—Many of you, in your rural rambles, may, during a moment of reflection or thoughtlessness, while standing on the parapet of a rustic bridge, have dropped a stone into the river flowing below, and have noticed the rings of waves projecting outwards. If at the same moment a hungry fish, in his desire to satisfy a natural craving, should dart or snatch at a fly on the surface of the water, a second series of rings of waves would be produced, and in such a case a careful observer would notice that where crest of wave meets crest of wave, there is a higher crest formed, and where hollow meets hollow a deeper hollow is formed. This super-position of wave on wave is called interference, and the interference of undulations plays a most important part in the phenomena of sound, of light, and of electricity. In electricity, wave upon wave can be super-imposed, either in waves flowing in the same direction or in waves flowing in opposite directions. The usual indication of the presence of electric waves is either by the attraction of a magnet or by the deflection of a needle. Here is a needle that is subject to the action of the passage of such waves of electricity. I send a current of positive electricity through the wire surrounding the magnet to which this needle is attached, and you see I get a certain deflection; I increase the strength of that wave by super-imposing another wave, and you see I increase the strength of the deflection. In the same way, if I reverse the direction of the current and send a negative current, I get a wave of certain strength, and if I double the strength of the current I get a stronger deflection. But if, instead of super-imposing one wave on the other in the same direction, I send one wave in one direction and another wave in the opposite direction, we get neutrality. This neutrality is a phenomenon corresponding very much to silence in sound or to darkness in light. Advantage is taken of this neutrality in duplex and quadruplex telegraphy in a way in which I will show you. It is usually imagined by those who think of duplex telegraphy that something crosses or passes in the same way that railway trains pass or cross each other. It is not at all necessary to conceive that anything whatever passes. For instance, here I have some glass balls placed in a row between two parallel wooden rods. If I take the ball at one end, say No. 1, a short distance from its normal position, and drive it along the rods back again, you will notice that a something, a form of force, passes through the other balls, and the one at the far end is by this developed motion forced a distance away from its neighbours. The same thing occurs if I take No. 12, No. 1 is displaced by the concussion. This resultant motion represents, and may be called, a telegraphic signal. If I am skilful enough to take No. 1 and No. 12, and let them return together, we shall see that they are both driven back simultaneously, the intervening balls remain undisturbed, and two such signals will be made. It is this latter phenomenon that I wish you to bear in mind as being analogous to the principle used in duplex telegraphy.

The next fact that I wish to impress upon you is that if a current of electricity have made paths open to it, it will always separate or spread itself among those paths in inverse proportion to the resistance which each opposes to its progress. The greater the resistance the smaller the current; the less the resistance the greater the current. If we have two paths or lines open to a current, and these two lines be of exactly equal resistance, the current will divide itself between them in exactly equal proportions. The next point, almost as self-evident as the previous one, but which time will not allow me to illustrate by experiment, is that the magnitude of the magnetism produced in the electro-magnet is simply proportional to the strength of the current passed through the magnet. The next and last elementary fact I have to bring before you is that the polarity or direction of the magnetism simply depends upon the direction of the current. On the wall I have two electro-magnets corresponding to each other. Around each are coiled two wires of exactly equal length and equal resistance. If I send a current through one of the wires I produce a deflection in one direction; if I send a current through the other wire I get a deflection in the opposite direction. You can imagine that one of these magnets is in Brighton and the other in London, with the connecting line wire between them. I want to arrange matters so that when I make a signal at Brighton I shall not in any way affect my own instrument, and to do so I divide my current in halves; one half goes through one wire of the magnet, and tends to deflect the needle in one direction, and the other half goes through the other wire of the magnet, with a tendency to throw the needle in the opposite direction. If by an arrangement, an artificial line or otherwise, I make these two halves exactly equal, no deflection of my needle takes place; but at the same time I do influence Brighton's needle. This gives us the first principle of duplex telegraphy. Of course, with a similar arrangement at Brighton, on the key at that end being depressed and a current divided in half sent through the electro-magnet, the needle there remains unaffected, while at the same time the needle at this end is deflected. Under these conditions, when currents are sent from both instruments signals or deflections are noticed at each station. It is by using resistance that we are able to make an artificial line attached to the second wire of the electro-magnet exactly equal to the line wire attached to the other wire of the electro-magnet. I have in a box here resistance equal to three or four hundred miles of line. Resistance is measured in ohms, an ohm being a unit used by electricians, and which represents about a yard of fine platinum wire, or about one-tenth of a mile of ordinary iron wire. The resistance contained in this box is divided into quantities ranging from one to two thousand ohms, any portion of which can be brought into use by simply taking out pegs representing the amount required. With this ready means at hand you will easily comprehend the facility with which a balance can be adjusted, and the opposition to the two halves of the current passing through the electro-magnet made equal. Whatever the distance of the line, whether between here and the Central Telegraph Station, or between here and Calcutta, or any distant place to which you choose to exert your imagination, the effect is just the same. To show you this system in actual working I have here instruments joined to a wire which passes through the streets to the Central Telegraph Station in the city. It is just as easy for us to connect a wire up in actual operation as to have assistants secreted in the adjoining rooms, which is sometimes supposed to be the case. I must first of all explain to you how telegraphic signals are interpreted into ordinary language. It is by means of what is known as the Morse alphabet, which consists of combinations of dots and dashes used to represent the ordinary letters. A dot and a dash, for instance, represent *a*, a dash and three dots represent *b*, dash dot, dash dot *c*, and so on throughout the alphabet. A dot itself is represented on the instrument before us by a short sound or beat, and a dash by a longer one. The sounds caused by the signals appeal to the consciousness through the ear, and are translated into the proper language. (The central station was called up, and a message was sent to him at the same time that one was being received from him, in illustration of duplex working.) The operation which you have just seen going on exactly corresponds with that which I described. The division of the current is arranged at each end by the use of a resistance box or "rheostat," and signals are sent without any interruption the one with the other. The duplex system of telegraphy is employed to a very large extent in this country, no less than 320 circuits being so fitted. The system is applicable to long and short lines, and even long cables in Red Sea, Indian Ocean, and across the Atlantic (in one case 2,400 miles long), have been successfully so fitted. Its application enables really more than double the amount of work to be done. This happens from the fact that no interruption arises from repetitions being required or questions asked, but the messages pass in a continuous stream in opposite directions almost without let or hindrance.

I would just mention another thing in answer to any who are surprised at errors taking place in the transmission of messages. The signals representing certain letters are very similar, and it is very easy for a faint dot to be missed or a short dash to be misinterpreted for a dot, and as the difference between the letter *t* (represented by a dash) and *r* (represented by a dot, dash, dot) is simply two dots, you will not be surprised at a message, informing some friends of the arrival of a party of ladies, "all right," was delivered as "all tight." And, again, a friend of mine in Manchester, whose wife wished to inform him that the "rash was all gone," was astonished to receive an intimation that the "cash was all gone." Many of these errors are simply due to the failure of a dot or the shortness or breaking of a dash, and the wonder is that with the more than one hundred million messages which are despatched every year in this country the percentage of errors is not greater than the small amount it is. I hope that, after the practical illustration you have just had of the extreme care and exactitude which is attendant on the accurate receipt of signals, you will deal lightly with errors of conversion of words such as "rash" into "cash," "right" into "tight," &c.

We have now to deal with another class, and that is called diplex telegraphy. Duplex telegraphy means sending two messages in opposite directions at the same time; diplex means sending two messages at the same time in the same direction. I have here two little instruments which give out their signals in musical tones, and I have also two keys attached to a battery in connection with them. There is only one wire between them. If I press down, say, key No. 1 I call up the sounder which emits a deep tone; if I press down key No. 2, I obtain a response from the sounder with a tone an octave higher. If I press both keys down at the same time both sounders answer, and whichever key is depressed it is always answered by its proper sounder. This power of sending two signals or messages at the same time in the same direction is called diplex telegraphy. It is difficult to explain how this is performed without the aid of a diagram, and it really requires some amount of courage to attempt the feat. Currents of electricity are developed in two ways; they differ in the direction in which they flow and also in their strength. The key on my right hand simply reverses the direction in which the currents flow every time it is depressed; the other key simply increases the strength of the current flowing, whatever may be its direction. A relay is also employed, which responds to a reversal of the current whatever its strength may be; and another relay responds to the increased strength of the current whatever its direction may be; so that on depressing the key to which the deep-toned sounder responds I send, say, a positive current; and if I touch the light sounder key I simply make that sounder speak by increasing the strength of that current. The same effect would be produced if I first sent a negative, and caused one sounder to respond, and then by increasing the strength of that negative current the other sounder would respond. The one relay is affected only by a strong current, while the other relay is affected by a strong or weak current, and is, therefore, influenced by either strong or weak reversals. (Mr. Preece here very minutely traced the different currents from the battery, through key and relay to sounder, so as to produce sounds by currents, varying in either direction or strength, and acting upon one or both sounders at the same time, or separately at will.) The increase of current was brought into action by means of the one key having attached to it a greater proportion of cells of the battery. That is diplex telegraphy.

How is this duplex used for quadruplex working? I showed you in diplex working that we simply split the current in two paths made exactly equal to each other. It matters not whether we have an or any number of relays in. Theoretically, it is possible to insert a great number relays, but practically only two are used; and in quadruplex working we simply duplex what I have called the diplex arrangement. On one end of the table before you we have two sides of the quadruplex, or one diplex; and on the other end of the table we have the other side of the quadruplex which also works diplex, and by this apparatus we are able to send four messages at the same time on the single wire, which you see goes from the table to the wall, and so proceeds to the Central Telegraph Station. The system, although difficult in description, is really wonderfully and beautifully simple, and if it were only requisite to follow out what I have just said, quadruplex working would be a very easy matter indeed. But there is such a thing in England as a climate, and there also is unfortunately such a thing as rain, and rain interferes considerably with the action of our duplex and quadruplex working. In a word, the effect of rain is precisely the same as reducing the length of our line. Supposing we have a wire between Liverpool and London, about 200 miles long, then when we have rain it covers the insulators with moisture, and the moistened insulators allow the current to escape to earth, and the result is just the same as though the line itself were reduced in length; and to compensate for this it is necessary to take out resistance equal to the loss. But by means of the rheostat it is not a very difficult matter to adjust a balance, and by carefully noting and watching storms of rain, snow, sleet, or fogs and mist, which are so troublesome to the working, a clerk has simply to vary his rheostat, and can so maintain working on wires of ordinary length. When we come to very long lengths of wire the weather disturbance becomes serious. There is another disturbance besides that produced by rain or weather, which is due to the existence in a telegraphic line of what is called electrostatic induction. This is a very hard word, but it really means something similar to the effect of friction in pipes on the flow of water or gas. When gas or water is forced through pipes, a quantity of it adheres to the sides, and produces a diminution of pressure due to friction. So, when we try to force electricity through a wire, a quantity of it adheres, as it were, to the sides of the wire, remains there as a charge, and diminishes the action of the current, and produces what is called retardation in signals. Retardation means really reducing the rate at which we work. If it is possible, say, between London and Aberdeen to work as fast as ever we like, when we attempt to work over a long submarine cable the speed diminishes very greatly indeed. Between London and Cork, and between London and Aberdeen we are at the present moment working practically as fast as the instruments will run, at the rate of about 150 words a minute, while through the Atlantic cable, with all their skill, they cannot work at more than 25 words a minute, and this is due to the disturbing element of electrostatic induction. To compensate for this it is necessary to make your artificial line exactly similar in all respects to your real line, and, with duplex circuits, this is done by inserting, in addition to the rheostat, a condenser. A condenser is simply a series of leaves of tinfoil separated by paraffined paper. A series of alternate paraffined papers and tinfoil readily comprise a Leyden jar, and such a Leyden jar would have the capacity of retaining a charge similar to that retained by the line; and it is only necessary to increase the size of the condenser until the same electrostatic capacity in it is obtained as is experienced in the line itself. Here is a condenser which has not the appearance of being a very formidable instrument, but it has sufficient electrostatic capacity to compensate for a line about 200 miles long.

We have in England at the present moment six circuits worked upon the quadruplex system. In America the system is carried out to a much larger extent, and sixty-three wires are fitted with it, and over these sixty-three circuits no less than eight million messages are transmitted annually. The question may arise in your minds as to why the quadruplex apparatus is not used as extensively in this country as in America, and the answer would be that in this country we have not the necessity for it. We have apparatus in use superior to the quadruplex. I mean the Wheatstone automatic, an instrument which was in its early stage brought before an audience of this institution. It enables us to transmit messages and news with enormous rapidity, and makes us quite independent of any of these supposed advanced inventions.

THE DUPLEX SYSTEM ON CABLES.

SIR,—I have read in your and other journals accounts of the lecture (which I had also the pleasure of hearing) recently delivered by Mr. Preece on the subject of Duplex Telegraphy before the Society of Arts. As it appears to me that an incorrect impression is likely to arise from certain statements of the lecturer, I beg to forward you for publication a copy of a letter I have sent to Mr. Preece,

And remain, Sir, yours faithfully,

J. MUIRHEAD, JUNR.

29, Regency Street, Westminster, S.W. *May* 28, 1879.

"DEAR SIR,—I was much surprised to hear you say in your lecture on Monday evening before the Society of Arts that, although I 'had duplexed some of the cables of the Eastern Telegraph Company in the Mediterranean and Red Sea on Mr. Stearns' principle, Mr. Stearns had only recently succeeded in duplexing one of the Anglo-American Company's Atlantic Cables.'

"The inferences naturally drawn from this statement are, first, that in duplexing the Mediterranean and Red Sea cables I had either infringed Mr. Stearns' patents or used them with his consent. Secondly, that I had not duplexed any one of the Atlantic cables, or any of the long cables east of the Red Sea.

"Now it is within your knowledge that I absolutely deny using any of Mr. Stearns' patents, and that for years past I have challenged that gentleman to take legal steps to decide and enforce his claims, but he has not thought fit to accept the challenge, or take any action in the matter.

"It is, I think, also known to you that besides duplexing several cables of the Eastern Telegraph Company in the Mediterranean and in the Red Sea, I have successfully duplexed the following long submarine cables:—

"Suez to Aden	1,500 miles in	1876.
"Aden to Bombay ...	1,800 "	" 1877.
"The Direct United States Cable, being the longest cable in existence	2,400 "	" 1878.
"Madras to Penang ...	1,300 "	" 1878.

"&c.

"Altogether my system has been applied and was in use upon upwards of 10,000 miles of cable before Mr. Stearns had succeeded in his long protracted efforts to establish duplex on an Atlantic or other long line.

"The method I adopt is distinctly described in my patents and has frequently been fully explained in the scientific and other journals, whereas, we are not yet informed of the means Mr. Stearns has recently employed to duplex one of the Atlantic cables; and it will be obvious to any disinterested electrician, who compares my specifications with those of Mr. Stearns, that I use no part of his inventions, as specified in his patents, but an apparatus, the novelty of which is not, and cannot be, disputed.

"You stated also in your lecture that Mr. Stearns had succeeded in obtaining twenty-five words per minute on the Anglo-American cable (1,800 miles). If you will be good enough to refer to the TELEGRAPHIC JOURNAL of May 15th, 1878, you will find it recorded that upon the Direct United States Cable (six hundred miles longer than the Anglo-American) I obtained a speed of twenty-five words per minute. Now our sending twenty-five words per minute on a cable 2,400 miles long is practically the same thing as sending about forty words per minute on the shorter cable 1,800 miles long.

"I do not ask you to accept my unsupported statements as to the essential difference between mine and Mr. Stearns' system. Sir William Thomson, Mr. Varley, Professor Jenkin, Mr. Latimer Clark, Professor Ayrton and others of the highest authority in the telegraphic world, have given their opinion that my method is quite distinct from what Mr. Stearns claims by his patents.

"Having regard to these well-known facts, I think I have some ground of complaint (as well on my own account as on that of my friends associated with me in the matter) in that you should have omitted to mention in your lecture upon the subject of duplex telegraphy the important work we had accomplished long before Mr. Stearns was able to duplex the only long cable he has ever been successful with, viz., the Anglo-American, and that you should have, in face of the high authorities I have cited to the contrary, stated as a fact that I had used Mr. Stearns' inventions.

"I trust you will do me the justice to read this communication at your next lecture, in order that some of the misapprehensions created on the last occasion may be removed.

"I also request the favour of this letter being published with your lecture in the proceedings of the Society.

"I am, dear Sir, yours faithfully,

"J. MUIRHEAD, JUNR.

DUPLEXING OCEAN TELEGRAPH CABLES.

ONE of the most important of recent advances in practical telegraphic operation is the duplexing of long ocean telegraph cables. The obstacles encountered and the difficulties to be overcome to accomplish this were numerous, and of such a character as at times to be discouraging. The problem of duplexing submarine cables was a much more difficult one to solve than even that of quadruplexing land lines. It was believed by even able electricians that so great were the obstacles encountered and to be overcome, that success was practically impossible. But scientific skill, experiments and perservering labor have been successful in solving even this most difficult problem, and there have been duplexed already nearly 15,000 miles of submarine telegraph cable. Among these are some of the longest cables operated, including the Direct and one of the Anglo-American Atlantic cables. After this practical solution of the problems involved, and with the experience already acquired, there will hereafter be no serious difficulty in duplexing any ocean telegraph cable whenever it shall become necessary.

Mr. Joseph B. Stearns has been engaged for some time in this work, and is to be congratulated upon the success which has finally crowned his labors. Dr. A. Muirhead, an English electrician and engineer of ability and reputation, has also devoted much time and study to the subject. To Stearns and Muirhead is the world mainly indebted for the successful application of the duplex system to submarine telegraphy. Many others have also been engaged in the work, and by the information derived even from their failures, final success has been facilitated.

In all, Dr. Muirhead claims that, assisted by Mr. Herbert A. Taylor, C. E., he has successfully duplexed some 10,000 miles of cable, which includes the Direct United States, and all the long cables of the Eastern Telegraph Company between England and Bombay. The first cable duplexed by the Muirhead system was the Marseilles to Bona section, in 1875; the latest was the Madras to Penang section of the Eastern Extension Telegraph Company, in the latter part of last year. Mr. Stearns has already successfully duplexed one of the longest cables of the Anglo-American Company, and it is understood will soon apply his system to the other cables of that company. At the last annual meeting of the company the chairman stated that the result had been to practically double the capacity of the duplexed cable for business.

It is claimed by Mr. Stearns that the Muirhead system is an infringement upon his patents, and it is understood that proceedings have been commenced by him to determine and establish his legal rights in the premises. The public, however, have but little interest in these legal complications, it is the success of the system that mostly concerns it.

The importance of this improvement will be appreciated in view of the great cost of making and laying cables, and of the fact that it nearly doubles the actual working capacity of cables already laid. The increased amount of business which can thus be transmitted within a given time, and the reduced demand for the investment of capital, will eventually reduce the expense to the public of ocean telegraph service. An increase of business is thus provided for without the necessity of duplicating cables at a large investment of additional capital. With the existing Atlantic cables duplexed and maintained in good working condition any probable increase of business for years to come can be met without the necessity of laying additional cables.

The details of Mr. Stearns' cable duplex system have not yet been made public, but we hope before long to be able to publish a description of it. The following extract from a description of the Muirhead system, prepared by Dr. Muirhead, and now being published in *The Telegraphic Journal*, will give the reader briefly an idea of the means by which the desired result is effected by him. He says:

"The system includes both a novel artificial line or model cable, and various adjustments for bringing the first part of the artificial line into close equivalence with the first few knots of the cable, and for perfecting the balance generally. Like a real cable, the artificial line is a continuous conductor of uniform capacity throughout its length, and is best named an induction resistance. It is formed by taking two strips of tinfoil and laying one over the other, but separated from it by a film of insulating material such as paraffined paper. One strip forms the conducting circuits of the artificial line; the other forms the outer or induction coating, and is connected to earth. The current is passed through the conducting strip or sheet in the same way that the current in the conductor of a cable is subjected to induction on the earth."

Engineer. July 1879

4600. DUPLEX AND QUADRUPLEX TELEGRAPHY, *J. Muirhead, jun.—Dated 12th November, 1878.—(A communication.)* 3d.

The improvements in duplex telegraphy consist in placing the battery between the true and artificial lines, and connecting the receiving apparatus between the middle of the battery and earth. In order to give a signal the battery is reversed. Thus, supposing copper to be connected to the true and zinc to the artificial line, while the key is at rest, the depression of the key will join zinc to the true and copper to the artificial line.

Engineer & Mining Journal Sep 7 1878

NEW MODE OF DUPLEX TRANSMISSION.*

By D. Morel.

Engineering & Mining Journal Sep 7 1878

Duplex transmission, based upon the differential system, presents the following inconvenience: if the resistance of one of the differential circuits alters, the current augments in the one and diminishes in the other. Now these two effects combine, and consequently this kind of transmission is more affected than the ordinary transmission by the variations of the resistance of the circuit. The author states that he has sought to remedy the defect in the following manner:

Two relays, the one with a polarized armature, have their coils in circuit with one pole of a local battery and with the line, the polarized relay being next the line. An operating key is connected to the circuit between the two relays. The armature contacts of the relays are connected through a local battery, the poles of which battery are also connected through the coils of the receiving instrument. The contact levers of the two armatures are connected to earth.

From the description it is easy to see that so long as the levers of the two armatures are in connection with their contacts no current will pass through the receiving instrument, and if either of these levers quits this position, the circuit of the local battery will be closed in the receiving instrument. The lever of the operating key, when at rest, communicates with earth; when it is depressed or raised, neither of the relays acts; but in both cases the circuit of the line battery is closed from traversing the bobbin of the unpolarized relay, the armature of which remains always attracted. For the other part, the polarized relay is previously arranged in such a manner that the passage of the current from the line battery does not cause the displacement of its armature.

A station will then be able to transmit without reproducing its signals on its own receiver, and this receiver will nevertheless receive the signals of the station corresponding.

The batteries at the two stations presenting to line poles of the same name, if the operating key at one end is at rest, the current from the opposing station will produce an effect upon the polarized relay inversely to that of the battery at its own end of the line, and its armature is displaced by, and the receiver will reproduce the signals made by, the station corresponding.

If the two stations work simultaneously, the currents emitted annul themselves, and the armature of the unpolarized relay ceasing to be attracted, the receiving instrument will still reproduce the signals sent by the opposing station. The experiments that the author has made with the Morse have been successful, and show that the return current does not produce important perturbations; and, in fact, the polarization of the relay nearest to the line having been over-excited by the passage of the current of the line of battery, the return current has no other effect than re-establishing the magnetism to its normal state. This system does not absolutely necessitate the use of a condenser. Though the different actions of the relays are made in a satisfactory manner with the Morse, they are not produced with sufficient strength to allow of their application to the Hughes receiver. There are, at certain times, delays that can be avoided only by making the relays more sensitive, and in this case the equilibrium is very unstable. The author has also tried the following arrangement: The receiving instrument has a double coil, the one in circuit from the transmitter (mechanically stamped paper) to line, the other in circuit from the transmitter to one pole of a battery, the same pole of which is also connected to the transmitter through a rheostat; the other pole of the battery is connected to earth. The lever of the transmitter, when in repose, is in connection with an earth contact, and the circuit of the battery is closed locally. One part of the current passes by the helix between the battery and the transmitter, the other part by the rheostat, or shunt, also placed between the battery and transmitter. This shunt permits the augmentation or diminution, at will, of the force which keeps the armature attracted. When the lever of the transmitter is raised, the current goes to line by traversing the helix in circuit between the transmitter and line in such a manner that the armature remains attracted. It results, that one is able to transmit without receiving his own transmission. When the two stations transmit simultaneously, currents are annulled and the armature raises itself. When the opposing station alone transmits, its current traverses the helix in circuit between the transmitter and line in an inverse manner to that of the battery at its own end, and the armature is still raised. They will receive, in the two cases, the transmission from the station corresponding; but the return current also releases the armature. P. H.

* Abstract of a paper in *Annales télégraphiques*, 1877, pp. 401-403. From the Proceedings of the Institution of Civil Engineers, edited by James Forrest, Secretary.

MUIRHEAD AND WINTER'S QUADRUPLEX SYSTEM (FOR LAND-LINES).

As is well known, the solution of the problem of quadruplex telegraphy depends upon a successful system of "diplex" telegraphy, that is, a method of sending two messages in the *same* direction at the same time; this system being obtained, the duplexing of it is an easy matter. Messrs. Muirhead and Winter in their system of quadruplex telegraphy have employed a somewhat novel method of "duplexing" their "diplex" system, which is worthy of publication.

FIG. 1.

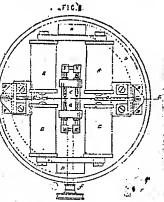

FIG. 2.
Section thro C.D.

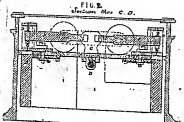

FIG. 3.
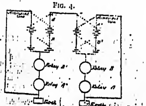
1st Position 2nd Position 3rd Position

FIG. 4.



In the diplex arrangement at the transmitting station the two keys are so arranged in connection with batteries that in the several positions of the keys the battery strengths flowing out to the line are as follows :—

Both keys at rest,	+ 3
Key B depressed, A at rest,	+ 1
Both keys depressed,	— 1
Key A depressed, B at rest,	— 3

The arrangement of the keys and connections by which this is effected will be described further on.

At the receiving station there is a polarised relay adjusted to break the local circuit when the current is plus, and to complete it whenever the current becomes minus; a local sounder or other receiver connected with this relay records the depressions of key A.

There is also in the main current at the receiving station a double tongued relay, which is used for completing the circuit of the sounder or receiver intended to respond to the movements of the key B.

This double relay, which forms an important feature of the system, is so arranged that in order that the local circuit should be completed, it is necessary for both tongues to be against their respective contact points. To accomplish this either the tongues are insulated and the contact between tongue and tongue caused to be completed through the contact points, which in this case are connected electrically with each other, or the contact points are insulated and the contact between point and point is completed through the tongues, which in this latter case are of course connected together.

The polarity and adjustment of the tongues is so arranged that the contact between one tongue and its point is only broken when the current is + 3, and that between the other tongue and its point is only broken when the current is — 3. With the intermediate strengths of + 1 and — 1 both tongues are in contact with their points, and the circuit of the relay is complete. Thus the local circuit is broken when the current is either + 3 or — 3, but it is closed when the current is either + 1 or — 1.

Both the contact points are fixed to the same carrier, and the arrangement is such that when once the contact points have been individually adjusted, their further adjustment for ordinary changes in strength of the currents is made simultaneously by one and the same motion of the carrier.

Figs. 1 and 2 represent respectively a plan and section of one form of the double tongue relay. In this form the tongues C C are polarised with like polarity by the permanent magnets N N. The tongues are insulated from the framework of the relay and from each other, and contact between them is established when both tongues are against their respective contact points, which are fixed to a single carrier and on one side of it; the screws on the other side of the carrier have insulated points.

The electro-magnets E, E, E, E, are polarised by the ends of the permanent magnets D D, the other ends of which polarise the tongues, so that all four poles of the electro-magnets have the same polarity.

The result of this arrangement is that, when the relay is acted upon by the currents + 3, + 1, and — 3 respectively, the tongues take up the respective positions shown by fig. 3.

After the first adjustment of the tongues, their further adjustment is made by moving the whole carrier *e e*, by means of the slow motion screw *f*, which works in a nut underneath the carrier.

It is evident that the action of any current passing through the coils of the electro-magnets, which are wound in the usual manner, is to cause the electro-magnets to act oppositely on the two tongues in consequence of the opposite polarity; thus, if a plus current tends to cause the one tongue to move in the direction of its insulated point, a minus current will have the same effect on the other one. The adjustment of the tongues is such that it requires a strength of + 3 to act thus upon the one tongue, and — 3 to act in the same way on the other tongue. If the current has either of the intermediate strengths of + 1 or — 1, the strength is insufficient to move either of them against the bias given them against their contact points, and consequently both tongues are in contact with their respective contact points, and the local circuit of the relay is complete. When the current changes rapidly from + 3 to — 3, the one tongue leaves its contact point before the other tongue has time to make contact. It is only when this change is retarded that any difficulty is experienced in working the local instrument B direct with this relay. If the instrument is a recorder the signals are perfect, as the effect of retardation is only to cause a slight trembling of the armature against its upper limiting stop, and is insufficient to affect the record. With sounders this is an inconvenience which can be remedied by using an extra local relay to complete the circuit of the sounder, the local circuit through the coils of which extra relay being completed by the double relay described.

In duplexing the "diplex" system a method of "double substitution" is employed. This system consists in placing the battery between the true and artificial lines, and connecting the receiving apparatus between the middle of the battery and earth. In order to give a signal the battery is reversed. Thus supposing copper to be connected to the true, and zinc to the artificial line, while the key is at rest, the depression of the key will join zinc to the true and copper to the artificial line.

In this arrangement perfect balance is obtained when the true and artificial lines are equal, and balance is perfectly independent of any changes in the resistance and electro-motive forces of the two halves of the battery, any inequality in which will merely cause a current to flow through the receiving instrument, but which current will remain the same whether a signal is being sent or not, that is, whether the battery is direct or reversed. The arrangement will be understood from fig. 4.

In this arrangement the keys B and B¹ separate the batteries into two portions, one of which contains 2 *n* cells, and the other *n* cells. When these keys are at rest the connections are along the continuous lines, and the two portions of the batteries are acting in the same direction, so that the current is 2 *n* + *n* = 3 *n*. When these keys are depressed they reverse *n* cells of the battery, so that there are only 2 *n* — *n* = *n* cells acting. The keys A and A¹, when depressed, simply reverse the current, whether it is 3 *n* or only *n* as before.

It will be seen that as far as the receiving instrument and batteries are concerned it is really the true and artificial lines which are affected by the reversing key. They mutually replace one another in two portions of the circuit external to the instrument and batteries. There has, therefore, been given the name of "double substitution" to this form of duplex working, which, although similar in appearance to the split battery system, differs from it essentially in principle, for whereas in the split battery system balance depends on the maintenance of a strict proportion between the electro-motive forces of the two halves of the battery and the resistance of the true and artificial lines, the balance in the method of double substitution depends only on the equality of the true and artificial lines, which, however, experience shows may differ widely without affecting the received signals injuriously.

The principal merits claimed for this plan are,—

1. Its very wide working range. The artificial line may be altered within wide limits without affecting the signals.

2. The fact that the plan requires no special winding of the coils as in the differential system.

3. That the sensitiveness of the relay is not reduced, and magnetic retardation increased by the shunting action of bridge wires, as in the bridge span.

4. The balance, as stated above, is not disturbed by variations in the electro-motive forces or resistances of the two halves of the battery, as is the case in the ordinary split battery system. In addition to this, the action of the signalling on the distant instrument is of course doubled.

All that is necessary to neutralise any current which may be passing through the receiving instrument in consequence of inequality in the two halves of the battery is to join the receiving instrument slightly out of the centre of the battery. In order to do this effectually two or more of the middle cells of the battery may be shunted by a slide resistance equal to about three or four times the resistance of the cells so shunted, the receiving instrument being joined between the contact point of the slide and earth.

It will be noticed that the peculiarity in this quadruplex system consists in the duplexing portion and also in the form of double tongue relay. The arrangement of currents for the different positions of the keys is identical with that employed by Mr. Gerrit Smith, in America, but the latter gentleman employs his most ingenious, yet simple, compound relay, in the place of the double-tongued relay, and with great advantage.

67

[37293.]—Electrical Duplex Working.—The querist is mistaken in his anticipations. The battery B¹ would not merely neutralise B as to its influence on the galvanometer G¹. This second battery has two circuits, the one considered in the question, and the other through the two galvanometers *via* their joint connection to B and the joint connection to E. If we conceive the two galvanometers as alike and oppositely connected as shown, in the first case they would be equally but oppositely deflected. On battery B¹ being connected the deflection in G¹ would be not neutralised but reversed, while that in G would be increased, the two batteries acting as one in multiple arc through it. The effects would depend altogether on the relative resistances.—Sigma.

[37293.]—Electrical Duplex Working.—I cannot see how "J. B." arrives at the conclusion that he does regarding this query. My opinion is that by inserting the second battery (assuming it to be of equal E.M.F.) the deflection on G¹ should be *nil*, as in the circuit where it is placed the tensions are opposed to each other, and, being equal, are therefore neutralised. The deflection on G, I would say, would be nearly doubled. I have not tried the experiment, but will do so, and report result in our next issue if different to above.—Ohm. Eng Mechanic July 25 1879

217,781.—Sextuplex Telegraphs. Thomas A. Edison, Menlo Park, N.J., assignor to Western Union Telegraph Company, New York, N.Y. Filed May 14, 1877.

The combination, in a telegraphic circuit, of a key to reverse the polarity of the current, a key to vary the strength of the current on the line, a vibrating reed acting to pulsate the current on the line, a key to shunt the main line and prevent the action therein of the pulsator, and three receiving instruments in the bridge, one operated by reversal of the current, the other by changes in the strength of the current, and the third by the pulsations of the current, substantially as set forth.

217,782.—Duplex Telegraphs. Thomas A. Edison, Menlo Park, N.J., assignor to Western Union Telegraph Company, New York, N.Y. Filed Nov. 14, 1878.

1. The method herein specified of producing an electric condition in the closed circuit of a telegraph line that will give a signal in a telephone by reversing the position in that line of an electro-magnet, secondary battery, or similar device, substantially as specified.

2. The combination, in a closed circuit, of a receiving magnet, a telephone, an electro-magnet, or its equivalent, and an apparatus for reversing the connections of the same in the circuit, a rheostat or resistance, a shunt to the same, and a key, substantially as set forth.

Edison's telegraphic quadruplex, says the Paris *Journal des Debats* of July 17, is about to be tried on the line from Paris to Brussel. This will be the first experiment with it on the continent of Europe. The system, as is known, is the only one that admits of the sending on the same line and at the same moment of four different dispatches. Engineering News Aug 2 1879

THEILER'S PATENT MECHANICAL DUPLEX (FOR LAND-LINES).

DUPLEX working either on the "differential" or on the "bridge" principle, is now universally known and understood, and if the essential features of these systems are referred to in the present article, it is only in order to show clearly in what respects this new duplex system differs from all others.

In both the differential and the bridge method, the current is split between an actual and an artificial line; and it is absolutely necessary that a certain ratio of current be kept up between the two circuits so as to produce a "balance." But, considering that the resistance and the electrostatic capacity of a line, from a multiplicity of causes, varies constantly and considerably (in bad weather the resistance may vary as much as 50 per cent. in one day), and that variation in the resistance and static capacity of the line means alteration in the adjustments of the apparatus, it must be conceded that duplex working, either on the differential or bridge principle, looks simpler on paper than it is found to be in practice.

In Theiler's mechanical duplex, the current is not split between two circuits, and as no equality of currents has to be maintained, variation in the resistance of the line, be it even as much as 100 per cent., does not affect the apparatus. There are no condensers, no rheostats, and the only adjustment required is that of the relay, just as in ordinary single working.

An explanation of the diagrams fig. 1 and fig. 2, which represent the *theoretical* construction of the apparatus, will show how signals, electrically neutralised by simultaneous sending from opposite stations, are recorded mechanically.

The key lever *e*, whose motion is limited by the stops *a*, *b*, carries a spring *f*, which is insulated at the point where it is fixed to the lever of the key which touches this lever at the extremity *h* of the latter. This spring impinges on the tongue *l* of the polarised relay *m*, *m'* when the key is depressed, but does not touch *l* when the key is at rest. The (polarised) relay may be of any form, but is preferably a "Theiler's,"* as that construction allows of a convenient and nice adjustment of the electro-magnet. The armature (which is induced at the centre *c*, so that both ends have similar polarity) is adjusted that the tongue *l* has a bias towards stop 2, stop 1 being in connection with the receiving instrument; Morse or Sounder.

Now when one of the keys (connected to earth) is depressed upon the front stop *b*, as shown in fig. 2, the end of the spring *f* touches the tongue *l*, and meeting an obstacle bends, and thereby breaks contact with the lever at *h*, consequently a current flows from the copper pole of the line battery through the tongue *l*, the spring *f*, the electro-magnet *m*, *m'*, to line, and entering the relay of station II. returns through the spring *f* and the lever *e* to earth.

The effect of this current upon the relay at station II., is an *increased* pressure of the tongue *l* against stop 2, which resists all tendency of the spring *f* to move the said tongue against stop 1,

FIG. 1.

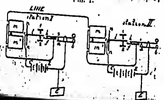

FIG. 2.

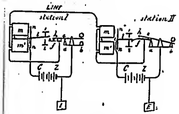

Fig. 3.

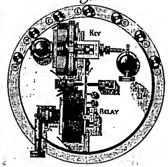

while the effect of the current upon the relay of the receiving station is exactly reversed, the current entering *m*, *m'*, from an opposite direction and causing the tongue *l* to move against the marking stop 1. Thus the outgoing current does not move the relay tongue of the sending but only of the receiving station. As both stations are connected exactly alike, the same thing will happen if station I. sends and station II. receives, both being in position to receive when at rest. It will be seen that every depression of the key tends to move the relay tongue mechanically towards stop 1, and is only prevented from doing so by the magnetisation of *m*, *m'*, which takes place the instant *f* touches *l*, and whereby the tongue is forced against stop 2.

If no current were to flow through the magnet of the sending station relay, then the key would produce its signals at its own station. Such is actually the case when both stations send simultaneously. Then the copper pole of station I. opposes the same pole of station II., and contact with earth being broken, no current goes to line; nothing now counteracts the tendency of spring *f* to push the relay tongue against the working stop 1, and thus, in the absence of any current, the signal sent by station I. is recorded by the mechanical actuation of the relay tongue at station II. by the key of the latter station; and *vice versâ.*

But the instant the key, say at station I. falls back while that at station II. remains depressed, the relay tongue of station II. also falls back, because the returning magnetization of that station's relay will overpower the pressure of the spring *f* and force *l* against stop 2, while the relay tongue at station I. will remain against stop 1 without any assistance from the spring *f*, because the direction of the current tends to keep the tongue on that side.

The actual construction of the apparatus differs somewhat from that illustrated by figs. 1 and 2. In order to render the motion of the lever *e* exact, decided, and as small as possible, it is preferable to effect it by means of an electro-magnet, and to use an ordinary key merely to make and break connection with that electro-magnet and a local battery. In practice, the point of contact of the spring *f*, with the lever *e*, and the point of contact of the said spring with the relay tongue *l* are made equidistant from the axis of the lever *e*, in order to make the momentary short circuiting of the line battery of as short a duration as possible. Fig. 3 represents the actual form of the apparatus, three-quarters of the real size. The adjustments of the key, once set correctly, are never touched, while the distance of the relay magnet from its armature and the bias of the relay tongue against the next stop can be easily regulated; the tension of the line spring *f* can also easily be altered; both these adjustments, however, need but very seldom be touched. A loop circuit of 200, and afterwards of 400 miles were, for instance, worked without altering the relay adjustment.

As the static charge from the line does not affect this system more than it does ordinary single working condensers are entirely dispensed with, and thus duplex working on this system with no rheostat, no condensers, and only the relay to adjust, is rendered as simple as ordinary single working.

In countries like England where duplex working has been extensively established for some time, and a change in the present system would necessitate change in a large stock of duplex apparatus, it will be difficult, perhaps, to get adopted *any* new duplex system until increased traffic calls for a greater number of duplex circuits.

But in countries where duplex working is only just gaining a footing, this mechanical duplex ought to have a splendid field. From its simplicity the system, also, appears particularly applicable to military field telegraphy. Where telegraphic lines are very long, two sets of the above apparatus, suitably connected to the "up" and "down" line, are used to act as a duplex translator.

We understand that the inventors of the Mechanical Duplex will shortly bring out a quadruplex on a similar principle.

Telic Journal Aug 15 1879

[We do not hold ourselves responsible for the opinions of our correspondents.]

To the Editor of THE TELEGRAPHIC JOURNAL.

SIR,—In your Journal of the 15th April, 1877, a simple and novel system of Duplex working, by J. J. Fahie, is described. Of the many advantages which this system is supposed to possess over other existing systems, as claimed by Mr. Fahie, is a very important one, and that is, that "*no condensers*" are at all required to balance the electro-static capacity of a line. This statement is supported by the results of actual trials on some of the telegraph lines in Persia.

To test the utility of the system, some careful experiments *without condensers* were made on the Indian lines. The results were, as anticipated, utter failures.

The failure was due to the fact that the electro-static capacity of the lines could not be balanced by the batteries as described by Mr. Fahie.

If you, or any of the practical electricians are of opinion that "*condensers*" are *actually not* required in the system, I shall deem it a great favour if an accurate explanation of the *theory* be inserted in the columns of your Journal.

69

You would also oblige me very much by letting me know the electro-static capacity of the condensers (in microfarads) employed by Edison in the *non-polarised relay circuit* of his Quadruplex system.

Also, I shall feel much obliged if you, or anybody else, will kindly inform me, through the medium of your Journal, on the utility of "Double Current" working, as applied to ordinary circuits, that is to say:—

1. Does "Double Current" working *actually* increase speed and the distance to be worked by eliminating the retardation due to the electro-static capacity of the line; and

2. Does the *negative* current employed in the system *actually lower* the insulation of the line? If the latter be correct,

3. What effect has it on the Quadruplex systems used largely in England, America, and other countries worked on the "Double Current" principle?

Yours truly,

"INDIAN TELEGRAPH."

[*No* duplex system, as far as we are aware, has yet been invented which has enabled condensers to be dispensed with when the apparatus comes to be worked on long circuits. In certain cases, it is true, owing to the mechanical construction of the apparatus the effects of the inductive discharge have been less felt, but they have not been neutralised, strictly speaking, but have only been *disguised*, and when a crucial test has been made, such as you have described, the result has proved that the effect anticipated has not been obtained, and a *correct* examination of the theory of the invention would have proved that the inventor's theory is false. Let all the different duplex systems invented be tried under exactly the same conditions, and we believe the effect of the inductive discharge will be found to be the same in all. Condensers, or equivalents to condensers, such as electro-magnetic shunts are, we believe, necessary in any case on long lines if duplex working is to be efficiently and economically (as regards battery power) carried on.

The non-polarised relay has been superseded, and with great advantage, by Gerritt Smith's compound relay. When the former apparatus was employed, the condenser used to "bridge over;" the kick of the armature varied according to the length of the line; about $1\frac{1}{2}$ microfarads may be taken as the average capacity required.

As regards "Double Current" working on ordinary circuits, the employment of the system does not increase the working speed by diminishing the inductive embarrassment, and even if it did diminish the latter the highest rate at which signals could be sent on any land line, even when retarded, would be much beyond what it would be possible to send by hand or at "key" speed. Double current working is used, not to obtain increased speed but to enable signals to be sent at all under the varying conditions of a long line. In the single current system if the line current varies to any great extent, a constant adjustment of the instrument and armature spring is necessary in order to obtain good signals, or, indeed, to obtain signals at all. With the double current system where polarised relays are employed, the tongue of the latter is set nearly neutral and being equally affected by the "marking" and "spacing" currents, works equally well whether these currents are strong or weak, that is, of course, within certain limits. Also, there being no spring for the current to work against, a very weak current will give good signals.

The negative currents employed in the system do not lower the insulation of the lines, they have no effect whatever on them.]

MESSRS. WINTER AND MUIRHEAD'S QUADRUPLEX IMPROVEMENTS ANTICIPATED BY MR. F. W. JONES.

Journal of Telegraph

CHICAGO, ILLS., Aug. 15.

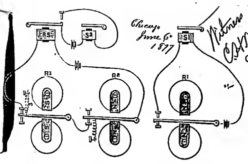
To the Editor of the Journal of the Telegraph:

In the issue of *The Electrician* for July 26th, 1879, appears a letter setting forth the novelty and efficiency of certain quadruplex arrangements made by Messrs. Winter and Muirhead. Not knowing at what date these gentlemen placed their improvement on record, I beg leave to inclose for the inspection of your readers an original diagram of a similar relay system invented by myself and witnessed by Mr. C. H. Wilson, June 7th, 1877. You may apply to my arrangement the exact description applied in *The Electrician* to the Winter-Muirhead system, and it will be found to fit exactly, inasmuch as they are identical.

"At the receiving station there is a polarized relay adjusted to break the local circuit when the current is plus and to complete it when the current becomes minus; a local sounder or other receiver connected with this relay records the depressions of key A. There is also in the main current (*circuit*) at the receiving station a double tongued relay which is used for completing the circuit of the sounder or receiver intended to respond to the movements of key B. This double relay *which forms an important feature* in our system of quadruplex is so arranged that, in order that the local circuit should be completed, it is necessary for both tongues to be against their respective contact points.

"To accomplish this either the tongues are insulated and the contact between tongue and tongue caused to be completed through the contact points, which in this case are connected electrically with each other, or the contact points are insulated and the contact between point and point is completed through the tongues, which in this latter case are of course connected together."

The action of the Winter-Muirhead relays under various operations of the keys and batteries having been described, said description being perfectly applicable to my system—the statement is made that



Chicago June 6th 1877

Witness C. H. Wilson June 7 1877

F. W. Jones

"on very long lines it may be necessary to use a local relay to work the recorder, the local circuit of this second relay being completed by the relay just described, but this will not be generally necessary;" and that "with sounders there is an inconvenience which can be remedied by using an extra local relay to complete the circuit of the sounder."

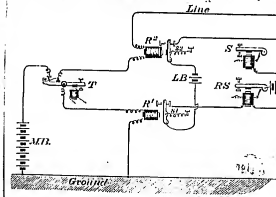
The inconvenient absence of a uniform movement of the relay tongues under different strengths of current is the reason why I turned my attention from the double tongued relay to one of more simple construction and perfect operation. This improved relay, well and favorably known as the Jones' relay, is based on all carefully studied principles of induction and magnetism, intelligently treated by Fleeming Jenkin, F.R.SS., Electricity and Magnetism, pages 71 and 284. It has already been generally adopted in the quadruplex apparatus used by the Western Union Telegraph Company.

F. W. JONES.

A Duplex Arrangement.

To the Editor of the Journal of the Telegraph.

HEREWITH I send you a diagram of a Duplex arrangement, made by me two or three years ago the exact date I regret I have not preserved. It has worked double perfectly for business, and as I have never seen any similar system described at home or



abroad, you may wish to put this upon printed record. The system is only remarkable for its simplicity, and the good character of the signals received at either station on circuits of ordinary length. The diagram shows the wires, instruments and batteries arranged at one station. R 1 and R 2 are single coil relays. T is an ordinary transmitter represented as *open*. R 1 has a tension of spring which allows the tongue to move when the battery of distant station is received. R 2 has a tension of spring holding the tongue against the force of the incoming current, but allowing it to move when both currents are simultaneously sent to line. S is an ordinary Sounder, operated by a repeating sounder RS on the up stroke. LB and LB' are local batteries respectively, whose functions will be well understood by an examination of the cut. When main battery MB is alone sent to line both relay tongues stand open, and Sounder S is not worked, but when the incoming current is received it operates sounder S either through relay R 1 or R 2, M R being open in the former case and closed in the latter. The currents from each station must not oppose each other, and it is practical to connect in way stations duplex, by duplicating the apparatus shown in the figure, and connecting the incoming line in place of the ground.

DUPLEX TELEGRAPHY.

To the Editor of The Telegraphic [Journal.]

Dear Sir,—I have read with much inte[rest the dis]cussion in your paper on the possibility [of working] Duplex without the employment of condens[ers.]

It should, certainly, be possible to re[produce by] mechanical means a signal which sho[uld] counteract and neutralise the effect of the [cur]rent in the relay, or other instrument empl[oyed for the] reception of signals.

The rate of magnetisation of similar elec[tro-magnets] in circuits of equal resistance, is much m[odified by a] slight inequality in the electro-static capac[ity of the] two conductors.

That of an artificial resistance of fine wi[re is] very small compared with almost any li[ne of tele]graph, and the latter would, in consequence, [absorb the] potential of the battery in a greater rati[o than the] other at the instant of making battery con[tact. There]fore, a compensating condenser is usually [attached to] the artificial line.

To produce the required effect without [condensers] I devised the following arrangement, and a[s] Messrs. Theiler, in their letter, do not m[ake any] suggestion of any plan prior to their own, th[ey may not be ac]quainted with the above, which I explaine[d]

TELEGRAPHIC APPARATUS IN USE IN THE BRITISH POSTAL TELEGRAPH DEPARTMENT.

XI.

Direct Writer Duplex System—(*continued*).

It has been generally understood and explained that the principle of the Duplex telegraph system involves the production of an exact balance on the receiving portion of the transmitting instrument, so that when the key of the latter is worked no effect is produced; this is only partially true, that is to say, a balance, but not an exact balance, has to be obtained. To obtain an exact balance is impossible, as can be seen by reference to fig. 50, which represents the general principle of the Duplex system as worked by the Post Office. Referring to this figure, let us suppose the key at the "Up" station to be depressed, then in order that no effect may be produced on the electro-magnet, M_1, at that station, it would be necessary that the resistance, R_1, be equal to:—the resistance of the line, plus the balancing resistance, R_2, at the distant station (which resistance will be equal to R_1), plus the resistance of the two coils of the magnet, M_2. It is obviously impossible that this can be the case, consequently exact equilibrium can never be produced.

In what way then do the balancing resistances enable duplex working to be effected?

Now, although the balancing resistances cannot enable a neutral effect to be produced on the electro-magnet at any one station when the key at the latter is worked, still it can enable a comparatively small effect to be produced on the same, an effect due to the difference in the strengths of the currents passing respectively in opposite directions through the two coils of the electro-magnet, and which can be counteracted by the tension of the armature spring.

But, it may be asked, what values should the balancing resistances have? The answer to this is—the adjustment must be such, that when signals are sent from the distant station, the strengths of these signals must not be altered, on alternately depressing and raising the key at the home station. The values of the balancing resistances necessary to produce this result are of course found by trial, their theoretical value it is unnecessary to determine.

Supposing the required balance to be obtained,

then the action of the apparatus will be as follows:—Supposing the key, K_1, at the "Up" station to be depressed, the one, K_2, at the "Down" station being in its normal position, then the current from the battery, E_1, will split, half going through the resistance, R_1, and the coil of M_1, represented by the . . . . . . line; the other half will go out to Line to the "Down" station and through the balancing resistance, R_2, from thence it will pass through the . . . . . coil of M_2 and back through the coil represented by the ——— line, to Earth, from there it will pass back to the Earth at the "Up" station, and through the ——— coil back to the battery. It will be noticed that the current passing through the two coils at the "Down" station does so in opposite directions, and as the coils are wound in *opposite* directions the full magnetic effect due to the two is produced, consequently the instrument responds. The currents passing through the coils at the "Up" station do so in the *same* directions, consequently a small magnetic effect only is produced, due to the two currents being of unequal strength. This small effect, as was explained, is counteracted by the tension of the armature spring.

If the "Down" station depresses his key whilst the "Up" station key is left in its normal position, then the instrument at the "Up" station of course responds.

Lastly, supposing both keys to be depressed, then since the two batteries have their opposite poles in connection with one another through the line, and through the ——— coils of the electro-magnets at the two stations, these batteries will send a strong current through the coils; also each battery will send a current through the balancing resistances and through the . . . . . . coils, but the strength of the currents going through the ——— coils will be about double that going through the . . . . . . coils, consequently both electro-magnets must respond.

In adjusting the balancing resistances or rheostats the telegraphist at, say, the "Up" station sends signals on his key to the "Down" station, and the latter adjusts his rheostat until he finds that his received signals do not alter in strength when he keeps his own key alternately depressed and raised. If there is too much resistance in the rheostat the received signals will be strong when the home key is at rest, and weak when it is depressed. The telegraphist is thus able to judge whether he must increase or decrease the resistance in the rheostat. When it is found that the signals are uniform the received signals are stopped, and the home station works his key, and increases the tension of his armature spring until his own signals cease to affect his apparatus. A similar operation is then gone through by the distant station.

Now, it must be obvious that when the Down station adjusts his rheostat, after the Up station has obtained his required balance, the latter must be thrown out again. This is true to a certain extent, but the amount by which it may throw the balance out is comparatively small. That is to say, for example, one hundred ohms wrong in the home rheostat would affect the home instrument more than would two or three hundred ohms wrong in the distant rheostat. If this were not the case the balancing would give a great deal more trouble than it actually does.

AUTOGRAPHIC TELEGRAPHY.

Mr. S. P. Dennison's Apparatus for Transmitting Messages in Facsimile.

Mr. S. P. Dennison, of this city, has recently patented a telegraph instrument by which messages are transmitted in facsimile almost as fast as the message can be transmitted by a good operator in the ordinary way by Morse key. The instrument has been upon exhibition for several weeks in this city and has attracted a great deal of attention. The fundamental principle of the apparatus is the same as that used in all preceding instruments for the transmission of a message in facsimile, namely the use of an ink for the original message which shall interrupt the electric current. The message is written upon thin tin-foil with an ink which forms a complete insulation wherever it makes a mark. The new feature of the apparatus is that instead of a stylus which travels back and forth over a line the width of the sheet upon which the message is written, a steel point is attached to the end of a vibrating arm hung between magnets, which swings back and forth across a tape of paper about the width of that used in the ordinary "tickers." Each instrument is provided with two of these vibrating points—one for sending and the other for receiving. Whenever the point passing over the original message upon tin foil meets with an ink mark, the current is interrupted for the second, and a black mark corresponding to the ink mark upon the tin is made upon specially prepared paper at the other end of the wire. The instrument is far more rapid than those which the Postal Telegraph Company had built a few years ago. When the receiving and sending needles are made to swing over a tape wide enough upon which to write several lines instead of one, as at present the speed will excel that of the best operators working with the old system. The advantages of being able to send a message in facsimile are too obvious to need mention, besides which the apparatus can be used by two merchants at a distance without the intervention of operators.

THE HARMONIC TELEGRAPH.

Recently certain users of telephones along the line of telegraph between this city and Boston have noticed a novel addition to the assortment of sounds which telephone wires pick up by induction from neighboring telegraph wires. The new sound is more musical than welcome, and is obviously made up of several distinct tones singing together, while each is independently interrupted by rapid breaks or short spaces of silence. These breaks correspond with the "dot and dash" sounds of the ordinary telegraphic instrument, so that the message may be spelled out by the interruptions of the singing tone. Tracing these sounds to their source, they are found to be due to a relatively new system of multiplex telegraphy now on trial on the Western Union Telegraph line between New York and Boston. The system is a development of Elisha Gray's original electro-harmonic or electro-acoustic multiplex telegraph, the early history of which is familiar to all who are at all acquainted with the investigations which led to the invention of the first speaking telephone. The tones of the harmonic telegraph are produced by the vibration of steel reeds operated by electro-magnets, the pitch of the tone produced being determined by the number of vibrations the reed makes in a second. The current operating one reed, when passed over a line, will set in motion at the further end a reed exactly corresponding to the first in rate of vibration, and cause it to yield the same note, while a reed tuned to a different note is entirely unaffected. When two or more reeds are sounding separately or simultaneously at one end of a circuit, their counterparts at the other end will exactly respond, each singing or keeping silent as its corresponding vibrator at the other end of the wire is started or stopped. Obviously any interruptions of the current passing through any transmitting vibrator will be produced by its corresponding receiving instrument, but not by any other in the series, causing clearly recognizable breaks in the singing tone emitted by the vibrator. The message spelled out by such interruptions of the current may be read by the receiver in the interruptions of the tone, or the receiving vibrator may be used as a relay in operating an ordinary sounder.

In the practical work, on the Boston line referred to, it has been found possible to send simultaneously by one wire, and analyze at the other end, four distinct tones, thereby transmitting four separate messages in one direction at one time. This offers a signal advantage over the quadruplex system, which transmits two separate messages simultaneously each way, but cannot send four messages one way. In cases of extraordinary pressure of business the full capacity of the harmonic system may be utilized in either direction. It is hoped that the harmonic system will ultimately make possible the simultaneous sending of four or five messages both ways on a single wire; in other words, four tone messages and one ordinary Morse message in each direction, or ten in all. In this way all the tones of the octave will be made use of, and that is the probable limit of the system, unless it be found possible to operate with fractional tones. Scientific American [illegible]

Electrician [illegible] 1880

3 THE DUPLEXING OF LINES BETWEEN GREAT BRITAIN AND INDIA.—The telegraphic communication between England and the Indian Empire is now in a state of thorough efficiency, the Eastern Company having duplexed their main lines throughout. The duplex system has been applied to the following sections:—Porthcurno and Lisbon, Porthcurno and Vigo, Vigo and Lisbon, Lisbon and Gibraltar, Gibraltar and Malta, Marseilles and Malta (two lines), Malta and Alexandria (two lines), Suez and Aden, Aden and Bombay. This gives an enormously increased capacity for business, and though the present daily traffic would a few years ago have seriously taxed the lines within working hours, the Indo-European and Eastern Company's cables have now a margin of capacity exceeding by many times the existing traffic. The efficiency of the staff also has kept pace with science, and we may mention that the daily average time for messages between London and Egypt is frequently only fifteen minutes, a result alike creditable to clerks and cables.

A PATENT has just been issued to Mr. J. E. Fenn, of the electrician's department, American Union Telegraph Company, for an important improvement in duplex and quadruplex working. As the Western Union owned the condenser patent, which is a particularly strong one, the American Union found that to enable it to work its long duplex and quadruplex lines it must have a substitute. So Mr. Fenn set about inventing one, and has just secured a patent for the same, as unassailable as is that of the Western Union. 30

INDUCTION ON TELEGRAPH LINES.

A TELEGRAM from Mr. Edison has directed our attention to the specifications of two patents taken out by him, one in this country and the other in the United States of America, which in his opinion anticipate the invention of the system for eliminating the effects of induction produced in a set of telegraph lines which was described by Professor Hughes before the Society of Telegraph Engineers, and which formed the subject of an illustrated article which appeared in this journal three weeks ago.* As we were the means through which publicity has been given to Professor Hughes's experiments, we have felt it incumbent upon us, in justice both to Mr. Edison and to Professor Hughes, to examine very carefully the two specifications referred to by Mr. Edison, so as to be able to form a perfectly unbiassed opinion of their bearing upon Professor Hughes's researches, that we might be in a position to place the facts before our readers, showing in what respects the two are similar to one another, where they run in a parallel direction, at what point they diverge, and in what particulars there exist essential differences; and, in order to facilitate the forming by our readers of a still more independent opinion, we have thought it best to reprint *in extenso* the full specification with the accompanying drawings of Mr. Edison's American patent, which will be found on another page, while we subjoin that portion of his British specification—also with the drawing—which has reference to the subject. The examination of these specifications in connexion with Professor Hughes's paper, which we published *in extenso* in the same issue as the article to which we have already referred,† enables, moreover, each of these eminent inventors to speak for himself in his own words and is again of assistance in the formation of a sound opinion.

The whole question involved in a case of priority of scientific discovery or invention, as well as in a case of the infringement of a patent, must rest on the all-important question as to what is claimed as the invention or discovery, and in what way that claim is interfered with by the claims of other parties. It is therefore necessary to determine at the outset of the present inquiry what are the claims of Mr. Edison which Professor Hughes has in his opinion interfered with, and what does Professor Hughes claim as novel in his experiments or in their results. It is due to Mr. Edison to point out that the compensation of induction in a telephone line by means of opposing to it counter inductions by special induction apparatus was included in one of his patents bearing date as far back as July 30, 1877, or close upon twenty months before Professor Hughes's paper describing his researches was published to the world; if therefore the question in dispute between Mr. Edison and Professor Hughes were the application of the broad principle of meeting induction by counter induction, then Mr. Edison's claim to priority would be indisputably established, and the only remaining question to be decided would be whether Mr. Edison had or had not been anticipated by any one else. Fig. 1 is an exact copy of the drawing

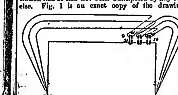

FIG. 1.

accompanying Mr. Edison's British patent to which we have referred, and we may mention in passing that in this very interesting specification a number of curious and, in some cases, very beautiful telephones, are figured and described as well as the present well-known form of the phonograph. The arrangement illustrated in the figure for eliminating the effects in a telephonic circuit of induction from neighbouring telegraph wires is so briefly referred to in the specification, that we quote it *in extenso*, and in so doing describe the figure in Mr. Edison's own words. "Where several line wires run near each other, the wire used for the acoustic or speaking telegraph is influenced by induction, and false sounds will be produced. I counteract this tendency by placing one or more electro-magnets 59 (Fig. 23) in the circuit of the speaking telegraph, and one or more electro-magnets 60 in the circuit of the adjacent wires, and bringing the opposite cores of 60 at such a distance from the cores of 59, that a certain magnetic action will be set up in 59 by induction in the opposite direction to the induction currents from the adjacent line or lines.

"By adjusting the distance between these magnets when the speaking telegraph is not in use, until there is not any sound at the diaphragm from the induction currents, then those currents will be neutralised, whether strong or weak, and will not produce any false sounds when the speaking telegraph is in use.

"I also employ double coils of wire for the same purpose, one coil being in the acoustic wire, and the other in the wire to be compensated."* Reference is again made to the same devices at the end of the specification in the last of the thirty claims as follows: "I claim as my invention . . . . . Thirtieth. In combination with an electric circuit containing instruments for reproducing sound, one or more electro-magnets, and one or more compensating magnets for neutralising the inductive effect of adjacent telegraph wires, substantially as set forth."†

It is clear, therefore, from the above that Mr. Edison's claim under that patent is no less and no more than that therein stated, viz., the employment of electro-magnets with magneto-electric inducting armatures for protecting a single circuit from the effects of induction of one or more telegraph lines, and it is also clear that although the compensation of induction by equal and opposite counter induction thrown into the same circuit is the broad principle involved in the invention, still it is not claimed as a part of the patent, for the very simple reason that it did not possess novelty. Again, it is equally clear that no claim is made to the discovery of a method by which a set of telegraph lines are compensated for induction each against the others. It is essentially a system of protection of one particular line against the inductive influence of one or a larger number of other lines, but offers no protection for any others in the group as between themselves. It is a special application of the principle of counter induction to a single circuit, and occupies to the whole question a precisely similar position to the twisted telephone line and return circuit, which was devised independently by Mr. David Brooks, of Philadelphia, and by Professor Hughes, and which is illustrated in Fig. 3 in our article on Professor Hughes's experiments.* Here a telephone circuit is made to protect itself against the inductive influence of other lines, or what is merely the converse of the case, a telegraph circuit is made harmless to other and neighbouring lines by a special system of erection, which is applicable but to one line of a group.

On the other hand Professor Hughes who, like Mr. Edison, makes no claim to the discovery, or priority of suggestion, of the elimination of induction by counter induction, claims to have discovered a method and invented a system by which any

† *Ibid*, page 13.

number of telegraph lines running in the same direction may be protected each against all from the effects of mutual induction, and we take it that this indiscriminate protection of all the lines constitutes at once the great value of Professor Hughes's invention, and its essential difference from any of the very beautiful devices invented by Mr. Edison for destroying the injurious influences of lateral induction in a telephone circuit, influences which without some such methods of compensation would have condemned the use of the telephone as a trustworthy instrument of communication.

Mr. Edison's American patent, which bears date February 21, 1878, *i.e.*, seven months after the date of that taken out by him for Great Britain, and of which we publish on another page the complete specification, deals with the subject of induction far more fully, in that the whole specification is devoted to the subject, while in the specification of the British patent it is merely touched upon among a large number of widely different subjects. The American specification is a highly interesting one, containing as it does several very pretty methods for the elimination of induction in telephone circuits by means of a combination of electro-magnetic and magneto-electric compensating inductors, and showing that both dynamical and statical electric induction may be got rid of or neutralised by similar arrangements, to which is added the use of condensers. The figures are so clearly explained in the text of the specification as to need no special description in this place; but we would invite more particular attention to Figs. 2 and 4, p. 277, as more conspicuously bearing upon the point at issue. The former is a diagram of one out of several arrangements devised by Mr. Edison for protecting a telephone line against the effects of induction of two or more telegraph circuits, such, for instance, as Nos. 1 and 2. This diagram bears a very close resemblance to that which we published† in illustration of the general principles upon which Professor Hughes bases his induction balance, and if the use of the latter were limited to the protection of one particular line against several others, the two devices would be very similar indeed, and we can well understand that Mr. Edison, having thought out and patented so beautiful a method of compensation, should, on seeing the first account of Professor Hughes's experiments, have been struck with the similarity, and should have assumed the two to be, for all the purposes of a patent, identically the same invention. The presence of the iron core is one point of difference between Mr. Edison and Professor Hughes's apparatus, although, as far as the principle is concerned, a not very important one, and we cannot help thinking that the removal of the iron would be accompanied with decidedly improved results. The counter-induction currents set up in the lines by the apparatus figured in Figs. 2 and 3 of Mr. Edison's specification (p. 277) are produced partly by electro-magnetic and magneto-electric induction, and partly by the ordinary dynamic induction taking place between the coils. The action of the first of these influences may be described as follows: Currents of electricity such as would be employed in the transmission of a telegraphic message would, in traversing the coil marked 2, induce magnetism in the iron core *g* which passes through all the coils and this increase of magnetic intensity in that portion of the core which is surrounded by the coil 3 would induce in that coil a series of currents of electricity which, by being thrown into the line with which that coil is in circuit, would either increase, or tend to neutralise, the effect due to the lateral induction of the line No. 2 with which the coil marked 2 is in circuit.

It is, however, quite probable that there is greater similarity between ordinary dynamical induction and electro-magnetic induction than at first sight appears, and that the latter is but a special case of the former; all dynamical induction being but an electro-magnetic effect due to variations in the intensity of the concentric lines of magnetic force circulating around a conductor conveying an electric current, and which have been so beautifully demonstrated by Dr. Silvanus P. Thompson, Professor of Experimental Physics in University College, Bristol.*

The second arrangement figured in Mr. Edison's specification would very satisfactorily accomplish, we have little doubt, the object for which it was designed, namely, the protection of the upper line against the inductive influences of Nos. 1 and 2, and it would in our opinion accomplish that object even still more perfectly if the iron core were removed, for Professor Hughes's experiments have shown that the presence of iron, or indeed of any conducting material within the coils, disturbs the balance and renders it next to impossible to obtain absolutely perfect compensation. This may be due to the impossibility of insuring the perfect homogeneity of the iron so as to produce uniform electro-dynamic effects in the two coils, but it is more probably due to the fact that the magnetisation of iron is essentially more sluggish than the dynamical induction between the lines, so that the induction currents and their corresponding compensating counter-induction currents are not isochronous, and therefore can only neutralise one another during the periods when their respective durations overlap.

Mr. Edison's drawing, Fig. 4, p. 277, although least resembling Professor Hughes's apparatus in general external appearance, is that which has the closest analogy to it in principle, because in this case the counteracting effect is produced by ordinary electro-dynamical induction, no iron core or other magnetic contrivance being introduced. In this case the wire to be protected, and the wire to be protected against, are wound side by side upon a cylinder of wood or other insulating material, and are connected to their respective circuits in such a way as mutually to neutralise their mutual induction. We would, in Mr. Edison's interest, attach more weight to this arrangement as bearing upon the merits of the case, than to all the rest of his specification put together; but in the absence of an arrangement by which the direction of one circuit is reversed at the moment of transmitting through it a signal, we cannot see how it can be protective against the influence of more than one line.

We believe that it is to Mr. Charles H. Wilson, of Chicago, that is due the honour of having been the first to point out an arrangement by which two telegraph lines may be perfectly compensated for induction, the one against the other, whichever of the two is constituting the primary circuit. This solution of the problem is as beautiful as it is accurate, and Professor Hughes has, we learn from his letter, which we publish in another column, acknowledged the priority of Mr. Wilson's work in the official reprint of his paper, which will appear in the next issue of the *Journal of the Society of Telegraph Engineers*. Mr. Wilson's arrangement is shown in the diagram, Fig. 2, and consists of a bar of soft

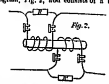

Fig. 2.

iron carrying two coils of insulated wire which are respectively placed in the circuits of the two wires. The effect, therefore of a current traversing one of the coils would be to induce in the other coil a corresponding magneto-electric current, and the coils are so connected to their respective lines that the currents induced by the coils are in a reverse direction to those induced by the lateral induction of the line wires. But, as a magneto-electric current so produced would in most cases produce a more powerful effect than that due to lateral induction, Mr. Wilson adopts the very ingenious device of short-circuiting each of the coils through a resistance box R and R', and these resistances are so balanced against one another, and adjusted for the relative influences of the coils and lines, that perfect mutual compensation is insured. Mr. Wilson also introduces into the circuits electro-magnets to act as condensers for prolonging the duration of the effects produced, so as to make his apparatus equally applicable for long as for short circuits.

There is certainly a remarkable similarity between Mr. Wilson's arrangement and that figured in the second and third figures of Mr. Edison's specification, but, as in Mr. G. B. Prescott's book on the Speaking Telephone and other allied instruments, full credit is accorded to Mr. Wilson for this invention, we take it that, bearing in mind the mutual scientific relationship existing between Mr. Edison and Mr. Prescott, the fact that it finds a place in the work of the latter, is an indication that Mr. Wilson's claim is equally admitted by Mr. Edison. The essential difference between the two arrangements is, however, that they accomplish different objects and are designed for two different purposes. Mr. Edison's arrangement is to protect one wire at the expense of all the others and regardless of what effects the latter have upon one another; for it is clear that although the upper wire is protected from the induction of the others, that evil is greatly increased in the others by the induction taking place among themselves. Mr. Wilson's arrangement is a perfect balancing of two lines, one against the other, but is powerless to protect either or both from the inductive effect of outsiders, or to protect outsiders from the influence of the lines to which the system is applied.

The respective arrangements of Mr. Edison, of Mr. Wilson, and of Professor Hughes represent the solution of three different problems; the first, how to protect one wire such as a telephonic circuit against the inductive influence of other circuits, without regard to their influence upon one another, or to the effect which such a system of compensation would have upon the unprotected lines. The second, how to balance the inductive effect of two lines, one against the other, so that whether either or both are being used the effects of induction taking place between them are eliminated; and the third, how to eliminate for a group of any number of lines the effects of induction, favouring one line no more than any of the rest, but insuring the protection for induction of each and all, whether one or more lines are being worked at the same time. It will be seen, therefore, that the three problems are essentially different and may be connected together for simplicity thus: Mr. Wilson's problem is a special case of Professor Hughes's, while Mr. Edison's is a special case of Mr. Wilson's.

But just as the problems to be solved possess essential differences, so the means employed by each inventor are equally distinct; and, indeed, it must follow from the nature of the considerations involved that the general nature of Professor Hughes's problem must necessarily involve very important differences in the method of solution to that for the more special cases.

What, in our opinion, constitute the characteristic points of distinction between Professor Hughes's balance and all other systems, are just those which he claims in his letter to us—which will be found in another part of the present issue—as being the essential features of his instrument, that is to say, 1st, the reversal of each coil at the transmitting station at the instant that a signal is sent through its corresponding line; and, 2nd, the proportioning of the length and distance apart of the compensating coils to the length and inductive power of the lines to which they are connected. It might, at first sight, be urged, as a weak point in Professor Hughes's apparatus, that if two or more circuits were being worked at the same time, and in the same direction, their coils would, from the construction of the instrument, be reversed together, and, therefore, would not be reversed with regard to one another; but Professor Hughes meets this difficulty by proportioning the strength of the battery to the length or resistance of its line, so as to have as nearly as possible equal strength of current passing through all the lines; for his experiments have substantiated in a remarkable degree the fact discovered and pointed out by Faraday nearly half a century ago,* but too often forgotten since, that the phenomenon of electrical induction between two conductors depends upon differences of electrical conditions existing between them, and that if the conditions of the two conductors be alike no induction can take place between them, and if two currents of equal strength be flowing through two equal conductors, they exercise no disturbing inductive influence upon one another, and this fact is demonstrated very

last week calling attention to those two specifications and stating his belief that they anticipate the experiments of Professor Hughes. It will be seen, therefore, that we are at the present moment in possession of far fuller information respecting what Professor Hughes claims, than respecting what is claimed by Mr. Edison, and we wish for this reason to caution our readers against forming an *ex parte* opinion of the merits of the case before the receipt of Mr. Edison's reply. It may transpire that Mr. Edison has supplemented his inventions by devices identical with or very similar to those by which Professor Hughes's apparatus is rendered applicable to all the lines of a group, and he may have further remarks to make which would altogether modify our opinion respecting the relation between the two inventions. We can only say for the present that our opinion has been formed from those sources of information that were open to us, and we shall have more to say on the subject when we are in possession of Mr. Edison's further opinion of the merits of the case.

THE "THUNDERER" EXPLOSION.

(*Continued from page 262.*)

In our number of last week we showed conclusively that the evidence of the eye-witnesses of the target practice on board the Thunderer was overwhelmingly strong in establishing the fact that two projectiles left the fore turret when the electric broadside immediately preceding the explosion had been fired. We will now bring forward the statements of William Caswell, who was in the turret at

public acknowledgment of all the labours of others which bear upon his own researches, that are within his knowledge at the time, or to which his attention has been directed afterwards; and the letter which we publish on another page from Professor Hughes shows, we think, that he is animated by the same honourable feelings, and will be found ready to acknowledge all that Mr. Edison has done. And the very moderate terms in which Mr. Edison has, in the telegram to which we have referred, stated his claim to priority indicates that he is actuated by no personal feeling, but is only anxious as a scientific man that his valuable contributions to an important branch of scientific inquiry should not be passed over by those publishing their discoveries in a similar field of research.

We have in the foregoing remarks arrived at our conclusions of course only from the data in our possession. We have on the one hand, (1) Professor Hughes's paper read before the Society of Telegraph Engineers, (2) his experiments which we have ourselves watched with great interest almost from their commencement, and (3) Professor Hughes's letter to ourselves which we publish in another column. And with respect to Mr. Edison, we have (1) his British specification of July, 1877, (2) his American patent of February 1878, which we also republish on another page, and lastly (3) we have his telegram of

* See ENGINEERING, page 210, Fig. 3, *ante*.

* See *Philosophical Transactions of the Royal Society*, Faraday's Bakerian Lecture, 1832.

number of telegraph lines running in the same direction may be protected each against all from the effects of mutual induction, and we take it that this indiscriminate protection of all the lines constitutes at once the great value of Professor Hughes's invention, and its essential difference from any of the very beautiful devices invented by Mr. Edison for destroying the injurious influences of lateral induction in a telephone circuit, influences which without some such methods of compensation would have condemned the use of the telephone as a trustworthy instrument of communication.

Mr. Edison's American patent, which bears date February 21, 1878, *i.e.*, seven months after the date of that taken out by him for Great Britain, and of which we publish on another page the complete specification, deals with the subject of induction far more fully, in that the whole specification is devoted to the subject, while in the specification of the British patent it is merely touched upon among a large number of widely different subjects. The American specification is a highly interesting one, containing as it does several very pretty methods for the elimination of induction in telephone circuits by means of a combination of electro-magnetic and magneto-electric compensating inductors, and showing that both dynamical and statical electric induction may be got rid of or neutralised by similar arrangements, to which is added the use of condensers. The figures are so clearly explained in the text of the specification as to need no special description in this place; but we would invite more particular attention to Figs. 2 and 4, p. 277, as more conspicuously bearing upon the point at issue. The former is a diagram of one out of several arrangements devised by Mr. Edison for protecting a telephone line against the effects of induction of two or more telegraph circuits, such, for instance, as Nos. 1 and 2. This diagram bears a very close resemblance to that which we published† in illustration of the general principles upon which Professor Hughes bases his induction balance, and if the use of the latter were limited to the protection of one particular line against several others, the two devices would be very similar indeed, and we can well understand that Mr. Edison, having thought out and patented so beautiful a method of compensation, should, on seeing the first account of Professor Hughes's experiments, have been struck with the similarity, and should have assumed the two to be, for all the purposes of a patent, identically the same invention. The presence of the iron core is one point of difference between Mr. Edison and Professor Hughes's apparatus, although, as far as the principle is concerned, a not very important one, and we cannot help thinking that the removal of the iron would be accompanied with decidedly improved results. The counter-induction currents set up in the lines by the apparatus figured in Figs. 2 and 3 of Mr. Edison's specification (p. 277) are produced partly by electro-magnetic and magneto-electric induction, and partly by the ordinary dynamic induction taking place between the coils. The action of the first of these influences may be described as follows: Currents of electricity such as would be employed in the transmission of a telegraphic message would, in traversing the coil marked 2, induce magnetism in the iron core *g* which passes through all the coils and this increase of magnetic intensity in that portion of the core which is surrounded by the coil 3 would induce in that coil a series of currents of electricity which, by being thrown into the line with which that coil is in circuit, would either increase, or tend to neutralise, the effect due to the lateral induction of the line No. 2 with which the coil marked 2 is in circuit.

It is, however, quite probable that there is greater similarity between ordinary dynamical induction and electro-magnetic induction than at first sight appears, and that the latter is but a special case of the former; all dynamical induction being but an electro-magnetic effect due to variations in the intensity of the concentric lines of magnetic force circulating around a conductor conveying an electric current, and which have been so beautifully demonstrated by Dr. Silvanus P. Thompson, Professor of Experimental Physics in University College, Bristol.*

The second arrangement figured in Mr. Edison's specification would very satisfactorily accomplish, we have little doubt, the object for which it was designed, namely, the protection of the upper line against the inductive influences of Nos. 1 and 2, and it would in our opinion accomplish that object even still more perfectly if the iron core were removed, for Professor Hughes's experiments have shown that the presence of iron, or indeed of any conducting material within the coils, disturbs the balance and renders it next to impossible to obtain absolutely perfect compensation. This may be due to the impossibility of insuring the perfect homogeneity of the iron so as to produce uniform electro-dynamic effects in the two coils, but it is more probably due to the fact that the magnetisation of iron is essentially more sluggish than the dynamical induction between the lines, so that the induction currents and their corresponding compensating counter-induction currents are not isochronous, and therefore can only neutralise one another during the periods when their respective durations overlap.

Mr. Edison's drawing, Fig. 4, p. 277, although least resembling Professor Hughes's apparatus in general external appearance, is that which has the closest analogy to it in principle, because in this case the counteracting effect is produced by ordinary electro-dynamical induction, no iron core or other magnetic contrivance being introduced. In this case the wire to be protected, and the wire to be protected against, are wound side by side upon a cylinder of wood or other insulating material, and are connected to their respective circuits in such a way as mutually to neutralise their mutual induction. We would, in Mr. Edison's interest, attach more weight to this arrangement as bearing upon the merits of the case, than to all the rest of his specification put together; but in the absence of an arrangement by which the direction of one circuit is reversed at the moment of transmitting through it a signal, we cannot see how it can be protective against the influence of more than one line.

We believe that it is to Mr. Charles H. Wilson, of Chicago, that is due the honour of having been the first to point out an arrangement by which two telegraph lines may be perfectly compensated for induction, the one against the other, whichever of the two is constituting the primary circuit. This solution of the problem is as beautiful as it is accurate, and Professor Hughes has, we learn from his letter, which we publish in another column, acknowledged the priority of Mr. Wilson's work in the official reprint of his paper, which will appear in the next issue of the *Journal of the Society of Telegraph Engineers*. Mr. Wilson's arrangement is shown in the diagram, Fig. 2, and consists of a bar of soft

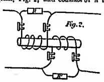

Fig. 2.

iron carrying two coils of insulated wire which are respectively placed in the circuits of the two wires. The effect, therefore of a current traversing one of the coils would be to induce in the other coil a corresponding magneto-electric current, and the coils are so connected to their respective lines that the currents induced by the coils are in a reverse direction to those induced by the lateral induction of the line wires. But, as a magneto-electric current so produced would in most cases produce a more powerful effect than that due to lateral induction, Mr. Wilson adopts the very ingenious device of short-circuiting each of the coils through a resistance box R and R', and these resistances are so balanced against one another, and adjusted for the relative influences of the coils and lines, that perfect mutual compensation is insured. Mr. Wilson also introduces into the circuits electro-magnets to act as condensers for prolonging the duration of the effects produced, so as to make his apparatus equally applicable for long as for short circuits.

There is certainly a remarkable similarity between Mr. Wilson's arrangement and that figured in the second and third figures of Mr. Edison's specification, but, as in Mr. G. B. Prescott's book on the Speaking Telephone and other allied instruments, full credit is accorded to Mr. Wilson for this invention, we take it that, bearing in mind the mutual scientific relationship existing between Mr. Edison and Mr. Prescott, the fact that it finds a place in the work of the latter, is an indication that Mr. Wilson's claim is equally admitted by Mr. Edison. The essential difference between the two arrangements is, however, that they accomplish different objects and are designed for two different purposes. Mr. Edison's arrangement is to protect one wire at the expense of all the others and regardless of what effects the latter have upon one another; for it is clear that although the upper wire is protected from the induction of the others, that evil is greatly increased in the others by the induction taking place among themselves. Mr. Wilson's arrangement is a perfect balancing of two lines, one against the other, but is powerless to protect either or both from the inductive effect of outsiders, or to protect outsiders from the influence of the lines to which the system is applied.

The respective arrangements of Mr. Edison, of Mr. Wilson, and of Professor Hughes represent the solution of three different problems; the first, how to protect one wire such as a telephonic circuit against the inductive influence of other circuits, without regard to their influence upon one another, or to the effect which such a system of compensation would have upon the unprotected lines. The second, how to balance the inductive effect of two lines, one against the other, so that whether either or both are being used the effects of induction taking place between them are eliminated; and the third, how to eliminate for a group of any number of lines the effects of induction, favouring one line no more than any of the rest, but insuring the protection for induction of each and all, whether one or more lines are being worked at the same time. It will be seen, therefore, that the three problems are essentially different and may be connected together for simplicity thus: Mr. Wilson's problem is a special case of Professor Hughes's, while Mr. Edison's is a special case of Mr. Wilson's.

But just as the problems to be solved possess essential differences, so the means employed by each inventor are equally distinct; and, indeed, it must follow from the nature of the considerations involved that the general nature of Professor Hughes's problem must necessarily involve very important differences in the method of solution to that for the more special cases.

What, in our opinion, constitute the characteristic points of distinction between Professor Hughes's balance and all other systems, are just those which he claims in his letter to us—which will be found in another part of the present issue—as being the essential features of his instrument, that is to say, 1st, the reversal of each coil at the transmitting station at the instant that a signal is sent through its corresponding line; and, 2nd, the proportioning of the length and distance apart of the compensating coils to the length and inductive power of the lines to which they are connected. It might, at first sight, be urged, as a weak point in Professor Hughes's apparatus, that if two or more circuits

beautifully and conclusively by Professor Hughes's experimental apparatus.

Summing up in a few words the foregoing remarks with respect to the relation between Mr. Edison's apparatus (see Fig. 2 of his specification, page 227) and that of Professor Hughes. (A). The two inventions are similar to one another (1) in the general application of the principle, claimed as original by neither inventor, of compensating induction by equal and opposite counter-induction, (2) in the employment of one inductor on the wire to be protected and one inductor on each of the circuits to be protected against, and (3) in the general external appearance of the apparatus. (B). The two inventions differ from one another (1) in the object which they are intended to accomplish, Mr. Edison's being designed for the protection of one specially favoured circuit against and at the expense of all the other circuits of the group, while Professor Hughes's protects any one member of a group against all the others, and all the members against one another, making it applicable to telegraphic as well as to telephonic circuits, (2) in the method by which the inductors are connected to their respective lines, for while Mr. Edison's are permanently attached (it not being stated to the contrary) in one position, those in Professor Hughes's are reversible, and must be reversed every time a current is sent through them, and (3) the essential differences of construction by which the lengths and distances apart of the coils in Professor Hughes's apparatus are proportional to the lengths and mean distance apart of the lines to be protected.

While, however (having formed the opinion from the data which we have been able to collect that the differences between the two systems are essential and conclusive as affecting the question of priority of invention) we cannot but feel that it is much to be regretted that Professor Hughes did not before publishing his experiments come across Mr. Edison's specification, which is of such a nature as to show the very valuable and important part which Mr. Edison has played in investigating the question of lateral induction. Had Professor Hughes been acquainted with what Mr. Edison had done, he could not have omitted to have placed it on record in his paper, as he has done the work of less important contributors to the science of the subject, and if Mr. Edison's very beautiful devices and interesting labours in this direction had been referred to in their place in the paper, we have no doubt whatever that no sort of difficulty would have arisen. It might be urged that it is the duty of an inventor before publishing a scientific discovery to make himself acquainted with all and everything that has been done in the same field by others, but to those who are acquainted with the labour of searching in the Patent Office for any particular device buried in some specification, of which neither the title, the date, nor the number are known, and especially to those who have to deal with the essential peculiarities of the patent system of the United States, this objection could not be seriously urged against any one who, like Professor Hughes, is engaged in scientific research, and whose time can be more profitably employed in other capacities. It is, however, undoubtedly the duty of any scientific discoverer to make the fullest and most public acknowledgment of all the labours of others which bear upon his own researches, that are within his knowledge at the time, or to which his attention has been directed afterwards; and the letter which we publish on another page from Professor Hughes shows, we think, that he is animated by the same honourable feelings, and will be found ready to acknowledge all that Mr. Edison has done. And the very moderate terms in which Mr. Edison has, in the telegram to which we have referred, stated his claim to priority indicates that he is actuated by no personal feeling, but is only anxious as a scientific man that his valuable contributions to an important branch of scientific inquiry should not be passed over by those publishing their discoveries in a similar field of research.

We have in the foregoing remarks arrived at our conclusions of course only from the data in our possession. We have on the one hand, (1) Professor Hughes's paper read before the Society of Telegraph Engineers, (2) his experiments which we have ourselves watched with great interest almost from their commencement, and (3) Professor Hughes's letter to ourselves which we publish in another column. And with respect to Mr. Edison, we have (1) his British specification of July, 1877, (2) his American patent of February 1878, which we also republish on another page, and lastly (3) we have his telegram of

SOEMMERING'S ELECTRIC TELEGRAPH.

The rapid success of Napoleon's Austrian campaign in 1809 was partly attributable to the good use he made of the optic telegraph, and when he had left the country the Bavarian minister suggested to Soemmering, a member of the Academy of Sciences of Munich, that the Academy of Sciences might advantageously turn their attention to the subject of telegraphy, the great advantages of which had been so completely demonstrated before them. Soemmering caught at the idea, and appears to have immediately recognised that electricity was the agent of all others calculated to render the required service. At that time the only known effect of an electric current which was suitable for the purposes of telegraphy, was the evolution of gas, and upon this he commenced to experiment. He first constructed a small apparatus. He made a cable of five wires insulated by sealing-wax. The ends of the wires, at one extremity of the cable, were connected to gold terminals in a vessel of acidulated water, and were marked *a*, *b*, *c*, *d*, *e* respectively. The other ends were placed, two at a time, to the terminals of a voltaic pile, composed of plates of zinc, silver coins, and felt soaked in dilute acid. The contact was followed by the evolution of gas from two of the gold terminals, and thus any two of the five letters could be indicated simultaneously. The possibility of effecting the transmission of words by this system having been demonstrated, Soemmering proceeded to construct the full-sized instrument shown in the annexed illustration, which was sketched from his original apparatus.

It consists of a receiver and transmitter connected by a cable of 35 insulated wires. Here the transmitter has 35 copper terminals in connexion with the conductors, marked with 25 letters and 10 figures. Any pair of these terminals could be connected to the poles of the voltaic battery by flexible connexions not shown in the figure, and thus a circuit established. The receiver had likewise 35 terminals; these were of gold, and were contained in a glass tank of acidulated water. To call the attention of the attendant an inverted spoon was arranged horizontally in the liquid, and collected the gases that were disengaged from certain terminals. When it became sufficiently buoyant it rose, and at the same time turned down a rod upon which there was loosely threaded a ball. The ball slid off, and, falling down a funnel, dropped into a cup at the end of a detent lever on a call-bell worked by clockwork, releasing the mechanism and putting the bell into action. In signalling the gas rose simultaneously from two of the gold terminals, the quantity from one being double of that from the other, and thus two letters were sent at once, it being understood that the one which evolved the greatest quantity of gas preceded the other in the written word. This apparatus was completed in August, 1810, but it was used without the call-bell in July, 1809. The first experiments were made over a distance of 38 ft., and then were rapidly extended to 1000 ft., and as soon as the inventor had perfected the insulation of his cable by caoutchouc dissolved in ether, to 10,000 ft. The telegraph was presented to the Academy of Sciences of Bavaria in August, 1809, to the Academy of Sciences of Paris in December of the same year, and afterwards to various royal personages, but no one took it up, and although it was twenty-five years before a practical system was brought out, yet no one seems to have tried to bring Soemmering's invention into a form from which useful service could be expected.

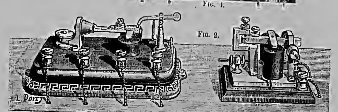

Fig. 2.

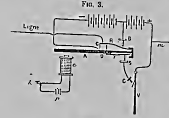

Fig. 5

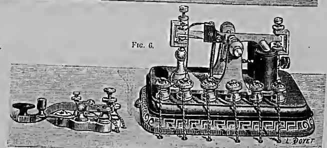

Fig. 6.

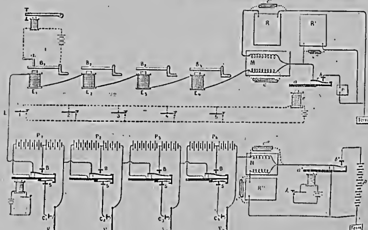

Fig. 7.

One of the most interesting exhibits in the American Section of the Paris Electrical Exhibition was the harmonic telegraph of Mr. Elisha Gray, the well-known Chicago inventor, and the jurors showed their high appreciation of it by awarding him a gold medal. In this system of telegraphy a number of different messages are sent over the same wire simultaneously from the same sending station, and this at the time the wire is being traversed by the ordinary Morse signal currents. Thus the Gray apparatus can be applied to a line which is already being worked on the ordinary system, without interfering with the latter. The reason of this is that the ordinary Morse signals are made by interruptions in a strong continuous current, whereas the Gray receivers are operated by relatively feeble vibratory currents. This principle is not quite a new one, as Mr. C. F. Varley, in 1870, patented apparatus for carrying it out in England; but the American inventor has very ingeniously brought it to a practical success. During test trials made on the Western Union Telegraph Company's wires between New York

The Iron Age – Oct. 16, 1884

Siemens' Telegraphic Cable Works.

A large number of the British Society of Engineers recently visited the telegraphic cable works of Messrs. Siemens Bros., at Charlton, where they had the opportunity of witnessing the various processes connected with the preparation of the materials used in the manufacture of these cables, as well as the manufacture of the cables themselves, and also the various kinds of electric telegraphic instruments and apparatus. From the reports of their visit we gather the following particulars concerning the method of making submarine cables:

The principal materials used in the manufacture of telegraph cables are copper wire, india-rubber, gutta-percha and hemp. In some cases the wire conductors are covered with india-rubber, and in others with gutta-percha, the cores being thus formed. The india-rubber is obtained in its raw state chiefly from Para, and the first process of manufacture is to rid it of its impurities. To this end it is cut into pieces and passed many times through rolls placed in pairs and running at differential speeds, so that a grinding as well as a squeezing action is obtained. A stream of water is continually running on the rubber, which carries away the impurities, and when the water runs clear it is an evidence that the cleaning process is so far complete. After this purification the rubber is dried at a moderate temperature, and afterward rolled into sheets of three classes. One consists of pure rubber sheets, while in the other two sulphur and other necessary ingredients are incorporated with the rubber. The sheets are then cut into strips or tapes ready for use in the covering machines. In the wire-covering department the conductors are incased in strips of these rubbers of one kind or the other, according to requirement, by being passed through machines in which the wire is, so to speak, sandwiched in between an upper and a lower strip, the edges being carefully trimmed off. In one machine wire was being coated with the pure rubber, while in another a conductor was being inclosed first in a white and then in a pink-colored rubber casing. The coverings are afterward solidified and made homogeneous by heat.

Another department is devoted to the covering of the conductors with gutta-percha, which, like the rubber, has to be first purified and prepared. The raw material in this case is obtained chiefly from Singapore, and is first cut up into slices by machinery. It is then soaked and softened in tanks of hot water, after which it is taken to a machine called a "ticker," or "devil," where it is shredded and discharged into hot water. It then undergoes complete mastication in special machines, whence it is transferred to hydraulic presses, where it is forced through strainers of fine wire gauze, which arrest all remaining mechanical impurities. It is again washed and masticated in boiling water. Various kinds of gutta-percha are afterward blended and finally rolled into sheets and stored. The wires are covered with gutta-percha by being drawn through machines having specially-constructed dies, in which the gutta-percha is contained under pressure and kept plastic by heat. As the covered wires leave the dies they pass through troughs of cold water and are led on to a second, and if necessary to a third, machine, according to the number of coats required. The insulated wire or core is conducted to the sheathing department, where it is first covered with hemp and afterward with iron wire by machinery. It is then passed through other machines, in which it is covered with two more layers of tarred hemp wound on in opposite directions. The cable is now completed, and as it is made it is stored in tanks, of which there are eight in the large tank-house, each tank being capable of holding 400 miles of cable. In a second tank-house there are eight more tanks of smaller capacity. From the tanks the visitors saw the cable being payed out to the telegraph cable ship Faraday.

An important feature in the manufacture of deep-sea cables is the testing, which is carried on throughout every stage from first to last, and on board the Faraday as the cable is being stored, so that it is impossible for a fault or flaw to occur without detection. The electrical testing-room of the works was, therefore, inspected with interest, as was also the pressure tank, which is a very ingenious contrivance for testing a cable core under the same conditions, as regards pressure, as those under which it exists at the bottom of the Atlantic in its deepest part. The apparatus consists of a small circular steel tank only about 30 inches internal diameter and some 5 feet deep, but weighing about 24 tons, the cover alone weighing 3 tons. Into this tank a length of about 2 miles of core wound on a reel or drum is lowered and the tank closed and locked by the screwed cover, the ends of the core being connected with the testing-room. Hydraulic pressure is then applied up to 4 tons per square inch—6 tons per inch can be applied if necessary—the core remaining under this pressure for about 10 minutes, during which the electrical testing is carried on. The machinery in what is known as the old cable shop is driven by a pair of compound horizontal surface-condensing engines of 180 horse-power indicated, that in the new cable shop being driven by a beam engine of 80 indicated horse-power. The cable works give employment to about 2000 men, another 1000 being employed in other directions.

MORQUET'S FLUVIOGRAPH.

(For Description, see Page 431.)

FIG. 1.

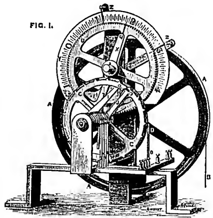

FIG. 2.

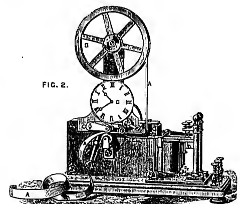


tinuous casing of plate metal. Mr. Fritz builds his blast furnace stacks in the same way. There is a considerable increase of strength and durability of shell with a given amount of material, and there is the advantage of making repairs from the outside when required. The cupola is lined up 7 ft. 6 in. in largest internal diameter, and 6 ft. at the tuyeres. There are eight tuyeres of 6⅜ in. diameter placed in a continuous row at 4 ft. 1 in. above the drop-bottom door. The blowing apparatus consists of four number 7½ Baker pressure blowers; the engine (compound) shaft runs direct through two blowers on one side, and two on the other, and makes about 90 revolutions per minute; belting is thus entirely avoided. The blast pressure is 1¼ lb. at the blower, and ¾ of a pound at the tuyeres. When the new Bessemer plant is running alone, three cupolas going continuously, and three blowers are required to supply it.

The cupola is charged as follows when cold:

	lb.
Bed, charge (coke)	800
" anthracite	8500
Iron	7500
Coke	700
Iron	7500
Anthracite	700

And so on, the fuel being reduced according to the judgment of the foreman as the furnace gets hot. The cupola bottom is usually dropped after a 48 hours' run, so that the patching around the tuyeres shall not be excessive, and on the average 10 lb. of iron ore melted with 1 lb. of fuel. Limestones and other fluxes are used as required. After each tapping of iron, the slag tap is opened and kept open until the iron reaches it. The spiegel cupola has 30 in. maximum internal diameter and 20 in. diameter at the tuyeres, which are four in number, and are 4 in. in diameter. This cupola is run with coke exclusively, and otherwise like the large cupolas.

The output of the new Bessemer plant, which was started in its present shape in March, 1881, averages about 3000 tons per week of twelve shifts; the plant has been worked at a higher rate of production. The heats of ingots run from 6¾ to 7½ tons according to the weight of rail. Fourteen inch ingots are bloomed to 7½ in. and cut into four to five single rail blooms for the roll mill. A 48 in. three-high blooming train with a single 65-in. cylinder, 8 ft. stroke, is nearly completed. This will roll much heavier ingots, and will be further described in another article.

TELEGRAPH CONDUCTORS AT THE ELECTRICAL EXHIBITION AT PARIS.

In a recent number we gave a full account of the new underground cable of Mr. Brooks, and in the present article we shall describe the lesser novelties in conducting wires of the International Exhibition of Electricity.

The highly insulating properties of paraffin are being more and more utilised in telegraphy. Mr. Brooks has succeeded in applying the liquid oil, and Mr. Henley is now manufacturing a submarine cable to be laid between Cuba and Belize in which solid paraffin is employed to heighten the insulation resistance. This material has for many years been used as the insulator for separating the tinfoil plates of the large condensers employed in signalling on submarine cables, and for making part of the artificial line in working telegraphs on the duplex system. When pure it has an enormous resistance to the passage of the electric current, and only its frail mechanical qualities have hitherto prevented its use as an insulator for submarine or subterranean cables. It is unfortunately soft and friable like wax, and therefore will not by itself stand the stress of laying and repairing as gutta-percha or india-rubber will. Mr. W. J. Henley, of North Woolwich, has, however, combined it with india-rubber in such a way as to increase the insulating power without impairing the mechanical properties of the rubber. In short, he manufactures an india-rubber covered core in the usual manner, that is, the wire is first covered with pure india-rubber, then with a "separator" of impregnated rubber, and lastly with cured rubber. The core so formed is cooked in the ordinary way, and afterwards it is cooked again in a bath of molted paraffin wax. The fluid paraffin assisted by the heat permeates the pores of the rubber and thus raises its insulation resistance. Some 380 miles of the new cable have already been made, and will shortly be sent out for laying.

Another and more thorough compound of india-rubber and paraffin wax is exhibited in the stall of Messrs. Latimer Clark, Muirhead, and Co., of Westminster. This new insulator is termed "nigrite" from its rich black appearance. It is the invention of Mr. Field, the well-known candle manufacturer, and consists of certain proportions of pure india-rubber and the black earth-wax called "ozokerit." The usual proportions are two parts of ozokerit by weight to one of india-rubber, a proportion which materially diminishes the cost of the compound. Para rubber and gutta-percha are both comparatively expensive, and the price of gutta-percha especially has risen very much of late years, owing to the increasing demand and the scarcity of the gum. Nigrite-covered wire, we are informed, can be turned out at a price 40 per cent. below that of good gutta-percha core. The mixture of the two substances, india-rubber and ozokerit, is brought about by mastication at a low temperature. The insulation resistance of the compound is very much higher than that of either india-rubber or gutta-percha, while its specific inductive capacity is considerably lower. It is therefore well adapted for insulating telephone lines and subterranean or submarine cables. It stands the atmospheric changes remarkably well, and hence is on demand in America for telephone wires and connexions. One drawback it possesses at present for use as an insulator for submarine cables, and that is its softness as compared with india-rubber and gutta-percha; but the inventor hopes to overcome this fault, and if so, he will have produced a valuable material for this end. Even now, however, it is eminently serviceable for leading wires, and lines for telephonic and electric lighting purposes.

Similar in looks to the nigrite is the black gum exhibited by M. Ernest Moerlot, 70, Rue Lafontaine, Auteuil, Paris. This novel substance is distilled from the bark of the white birch tree, and hence is called "French gutta-percha." The inventor holds that it possesses high insulating properties, entitling it to replace the ordinary gutta-percha and india-rubber for telegraphic use. As a product of our own temperate climate, and of one of our common forest trees, it at least deserves the trial and encouragement of European electricians. Perhaps, too, if the search were continued some other vegetable gum, equally good, or better, might be discovered among our native flora.

The cables of MM. Berthoud, Borel, and Co., as manufactured by the Société Anonyme des Cables Electriques, 33, Boulevard Haussmann, Paris, are also worthy of note as another application of wax paraffin to insulating conductors for telegraphic, telephonic, and electric lighting purposes. They are distinguished from other sorts of cable by their construction and low price. The insulator consists of equal parts by weight of paraffin wax and resin. The conductor is served with cotton and then steeped in the molted insulating compound. It is protected by a pipe or envelope of lead, and over that a layer of coal-tar pitch, then a second lead pipe thicker than the first. Lastly, if it is required, an armour of iron wire covered with tarred tape is served over all.

The insulation resistance of a single wire insulated in this manner is about 5000 megohms per kilometre at 16 deg. Centigrade. Single and double wire conductors of this kind are now used for telephonic purposes in Paris. A cable having seven separate conducting strands, each half a millimetre in diameter, is employed for telegraphy, and the mean insulation resistance per kilometre is as high as 29,000 megohms, while the inductive capacity is 0.1 microfarads for the same length. The diameter of the insulated core for such a cable is about ⅓ in., and the external diameter of the pipe is about ⅔ in. The quoted price is 1700 francs per kilometre. For telephonic and electric lighting lines the price is relatively lower, owing to the lower insulation required. For example, a telephonic cable comprising six conductors, each seven-tenths of a millimetre in diameter, costs 800 francs, while one comprising two conducting wires is only 400 francs per

82

Eng. Mech. + World of Science - July 18/84

MICHELA'S STENO-TELEGRAPH.

THE attempts which have hitherto been made to enlist the telephone in the work of the press have not been altogether successful even in London, where every facility exists and the distances are short; but there is a possibility that the stenograph telegraph of Signor Michela, of Ivrée, will eventually, either by itself, or in an improved form, supplant the present systems of telegraphing. In spite of the wonderful accuracy and speed with which the trained operators despatch long messages by means of Wheatstone's recorder, it is obvious to the thoughtful observer that there is something radically defective in the whole system of telegraphy, for, so far from a single signal representing a word, the majority of the letters which go to make up a word require for themselves two or more signals or marks. The expert telegraphist is a living exponent of what training can do to render possible what might easily be considered impossible; but it cannot be admitted that the present system of telegraphing, perfect as it may be, so far as it goes, is finality. The telephone, over short distances, and with suitable arrangements, beats the telegraph out of the field, but it has the defect that it leaves no record of what has been transmitted; the printing and recording telegraphs have that great advantage, they give up their messages in permanent shape, which can be preserved for future reference and verification. Just, however, as shorthand is to long-hand, so is steno-telegraphy to the string of dots and dashes so puzzling to the novice. The aim of Signor Michela is, in fact, to telegraph by means of a keyboard instrument any speech, no matter in what European language, at the same speed as it is delivered, or say, at the rate of 10,000 words in an hour. Michela's apparatus has been in use in the Italian Senate, and, from a pamphlet before us, written by M. Cassagnes, we learn that experiments with it can be witnessed every day at certain hours at No. 1, Rue Rossini, Paris. It goes without saying that Michela's machine works on the phonetic principle, and depends mainly for its success on the ability which the inventor has disclosed in grouping into series, and representing by combinations of signs, all the phonetic sounds emitted in any language. As soon as the operator hears the words, he decomposes them as it were, and prints their graphic representations in short horizontal lines on a paper band about 1¼in. wide. That is a stenographic record, but, at the same time as the signs are being printed on the paper, they may be telegraphed to a distant station. The machine consists of two parts—the printing mechanism and that for the automatic forwarding of the paper. The latter is of no special character, but the printer consists of two keyboards having 10 keys each (six white, four black); these keys press on 20 studs which are, by a system of levers, connected to as many styles, which carry the signs or characters to be imprinted on the paper. It is stated that a skilled operator can take down with Michela's apparatus 200 words per minute in any language he knows—a speed which is more than sufficient to follow the fastest speaker. For something like three years the system has stood the practical test, so far as stenography is concerned, and now the machine has been connected electrically with an apparatus for transmitting the signals to a distant station as fast as they are made, so that, if the receiver can translate the steno-telegraphic signals with rapidity, a speech might be read at the distant office as fast as the speaker himself delivers it. It is preferred, it appears, to keep each machine for its own special work, that is, the receiving instrument is not used as a transmitter, nor the transmitter as a receiver. The receiver, in fact, has the printing styles but not the keys, the styles being actuated by magnets, excited by currents sent from the transmitter. This arrangement has been adopted because the machine could be made lighter or to require less force to actuate it, and because the use of a combined transmitter and receiver would have interfered with quadruplex and multiplex working. Without details of the mechanism, which indeed would be of little use without diagrams, it must suffice to say that each key may be considered a true Morse key, and the board, therefore, represents a set of 20 Morse instruments, which combined, according to Michela's stenographic method, give a transmitting speed much higher than that of any existing telegraph. The value of this device, assuming that it works successfully in practice, cannot be over-estimated; for, to take only the case of Parliamentary reports, it will be possible to send to different newspaper offices in distant towns the actual words of a speaker as fast as he delivers them. The telegraphic shorthand in which they are delivered will need translating, but it is stated that any intelligent person can learn to do that in fifteen days, while to acquire the art of transmitting with facility will need a study and practice of six months. In any case the stenographic signs will be, at least, as easy to learn as the single-needle motions or the dots and dashes of the recording instruments, and, whether Michela's device does or does not meet all requirements, it certainly points out the direction in which inventors should look for a probable improvement in the present system of telegraphy.

Iron - Jan. 13/82

THE NEW ATLANTIC CABLE.—The steamship *Faraday* left the works of Messrs. Siemens Brothers at Charlton on January 10, with the last portion of the new Atlantic telegraph cable, which is to be forthwith completed for the American firm of Goold and Co. The cable is of special kind and remarkable for its strength, the shore end weighing 18 tons per mile and the deep sea and intermediate sections being to correspond. More than 1100 miles have been taken on board at the rate of 50 miles per day, and the cable, when completed, will be 3000 miles in length. The *Faraday* has made three voyages on the same work, leaving the end of the cable on each occasion buoyed in the Atlantic, where it has endured the storms of the past year without the slightest injury.

Iron A TELEGRAPHIC CONTEST. Nov. 7/84

A REMARKABLE contest for fast telegraph transmission took place recently at New York, at the offices of the Western Union Telegraph Company. The prizes offered for competition were three in number, the first being a gold medal, the second a silver medal, and the third a decorated telegraph key. They were given by Messrs. J. H. Bunnell & Co., of New York, and the only condition was that the Morse steel lever key should be the one used. The prizes were for clearness of character and speed combined. At eleven o'clock, when the contest began, over one hundred leading operators and telegraph managers were present. On a printed slip was the work to be done. This consisted of 500 words, 15 periods, and 4 commas,—in all 2,368 characters. The messages were sent on a local circuit. There were ten competitors, all of whom did remarkable work, and at one o'clock the contest was finished. Shortly afterwards the judges announced their decision, which awarded the first prize to Mr. W. L. Waugh, for superior work, each letter and character being perfect, time 11 minutes 27 seconds; the second prize to Mr. W. M. Gibson, for good work, time 11 minutes 3 seconds; and third prize to Mr. F. J. Kihm, for fair work, time 10 minutes 32 seconds. Mr. Waugh belongs to the Commercial Telegram Company, Stock Exchange, Mr. Gibson to the Bankers' and Merchants' Stock Exchange, and Mr. Kihm to the United Press Association. The most remarkable time on record was that of Mr. J. W. Roloson's, an operator of the Bankers' and Merchants' Company. His time was 10 minutes 10 seconds, or at the rate of about 50 words per minute, but his work was too indistinct and unreadable to obtain a prize.

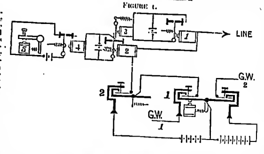
83

Montreal June 1, 1884

DUPLEX AND QUADRUPLEX TELEGRAPHY.

A NEW INVENTION BY R. B. TOYE, Superintendent G. N. W Telegraph Co'y., TORONTO.

FIGURE 1.



For the present purpose, we will suppose that the transmitters are at one end of the line and the rest of the apparatus at the other. Transmitter No. 2 sends the weaker current, say one-third of the whole, from the short end of the battery to line, transmitter No. 1 sends the stronger current from the long end the other two-thirds and both together send the whole current of the battery to line. Relay 2 is adjusted the usual way to be operated by the current from the short end, while relay No. 1 is adjusted too high to respond to it. When the stronger current from the long end of battery is sent to line, relay No. 1 responds but No. 2 does not its armature being kept open by the armature of No. 3 falling back, its local being opened by the arm of No. 1. When both transmitters are closed, the additional strength closes relay No. 2 (as well as No. 1) by overcoming the spring of No. 3.

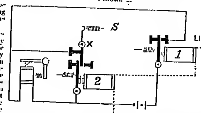
Now suppose both transmitters and relays are closed, if transmitter No. 1 is opened, the long end of battery is taken off line, relay No. 1 opens and simultaneously allows local to retain No. 3 closed, and the short end of battery keeps relay No. 2 closed. Next, when both transmitters are closed, and transmitter No. 2 is first opened, the short end of battery is taken off line. Relay No. 1 remains closed but the arm of No. 3, its circuit being still kept open, opens Relay No. 2, lastly, when both transmitters are opened, there is no current to line and both relays open.

Relays No. 1 and 2 are duplex relays of the usual pattern, although for the sake of simplicity the double wires and artificial line are omitted in the diagram. When both transmitters are open, the line is to ground via spring and arm of No. 2 and spring and post of No. 1 transmitter to G.W. 1.

G. W. 2 puts the long or short end of battery to ground according to the position of the armature of transmitter No. 1.*

When both transmitters are closed the route is from G. W. 2 through spring and back post of transmitter to battery thence through whole battery (the tap wire being disconnected from line at the front spring of transmitter No. 1) to post and spring of No. 2 and line.

FIGURE 2.



Magnets 3 and 4 are dispensed with in this plan, making the system almost as simple as that of a repeater:—

Instead of checking the action of the Armature of Relay No. 2 by holding it back by the arm of 3, it is allowed to play as moved by the currents, when it reaches arm X, under the impulse from the long end of the battery it cuts out the magnets of Sounder 2, so that it fails to respond, but spring S allows it to go no further. When the whole battery is sent to line spring S is overcome and arm X moves off its back stop, so that the battery operates Sounder 2 which then closes.

Now let us suppose the short end of battery is to line, transmitter 2 being closed, which of course closes Relay 2, Relay 1 is open being adjusted too high to respond. Next we will suppose transmitter 1 is being worked sending the long end of battery to line; as the short end is already to line, the whole battery goes to line, every time transmitter 1 is closed:— At first sight it would seem that when the arm of Relay 1 closed on arm X, local magnet 2 would be cut out and consequently open, and such would be the case if the arm of 1 rested against the arm X, but here it has another part, and that a paradoxical one to play, as it not only cuts magnet 2 out, but *simultaneously cuts it in again*, (by moving arm X off its back stop,) in so short a fraction of time, that the cutting out actually does not take place at this particular time, and consequently Sounder 2 remains closed. Then on the back stroke of Relay 1 the same apparently paradoxical operation takes place in the opposite direction, arm of Relay 1 in moving back leaves arm X on its back stop, apparently cutting magnet 2 out but at the same instant it breaks contact with it, so that the local circuit remains complete through the arm of Relay 2.

The above is sufficient to give the key to the whole action of the apparatus: perhaps we may return to the subject again.

Experiments in Synchronous-Multiplex Telegraphy.*

BY PROF. EDWIN J. HOUSTON.

A most extraordinary experiment, which is not devoid of practical bearings, has quite recently been made by Mr. Patrick B. Delany with his synchronous-multiplex telegraphic system, which is now in operation between Boston and Providence, a distance of about fifty miles.

As the experiment about to be described almost challenges belief in its possibility, I desire to state that I have seen it myself and can vouch for the accuracy of the facts herein stated.

Wishing to try the adaptability to the synchronous system of the automatic repeaters employed by other telegraphic systems, whereby great distances are overcome, Mr. Delany, on three different occasions during the past two weeks, successfully employed such repeaters with his system, the last trial, viz., that on Monday, the 14th of July, being witnessed by myself.

One of the two wires erected by the Multiplex Company between Boston and Providence was divided into six separate and distinct Morse circuits. The first of these circuits, which we will call No. 1, was operated to Providence, at which place the receiving relay, on that circuit, was connected to the transmitting instrument on No. 2 circuit. In Boston, the receiving relay of No. 2 circuit was connected to the transmitting instrument of No. 3 circuit. In Providence, the receiving relay of No. 3 circuit was connected to the transmitting instrument of No. 4 circuit. In Boston, the receiving instrument of No. 4 circuit was connected to the transmitting instrument of No. 5 circuit. Finally, in Providence, the receiving relay or instrument of No. 5 circuit was connected to the transmitting instrument of No. 6 circuit. Under these arrangements the transmitting instruments at both stations were operated by the receiving relay on the other circuit the same as if worked or operated by an operator; in other words, the six separate and distinct circuits established by the synchronizing apparatus between Boston and Providence were arranged so as to form in reality a continuous wire stretched six times between Boston and Providence, with both of its free ends in Boston.

Mr. Delany then transmitted a message on the No. 1 circuit, from Boston to Providence, which was automatically retransmitted from Providence to Boston on No. 2 circuit; again automatically retransmitted from Boston to Providence on No. 3 circuit; again automatically retransmitted from Providence to Boston on No. 4 circuit; again automatically retransmitted from Boston to Providence on No. 5 circuit, and finally automatically retransmitted from Providence to Boston on No. 6 circuit. Or, in other words, the message sent from Boston on the first circuit, went to Providence, came back to Boston, again went to Providence and came back to Boston, when it again went to Providence and came back to Boston, at which final station it was clearly read by an operator without the loss of a single character, or the slightest impairing of its original clearness, and without the aid of any person except the transmitting operator on the No. 1 circuit in Boston and the receiving operator on the No. 6 circuit in Boston. All this was done over one and the same wire, so that the message traveled in its back and forth journeys between the two cities, about three hundred miles, or six times the distance between the two cities.

A reference to the drawing will render the preceding explanation clearer. The synchronized distributing instruments *A* and *B*, situated at Boston and Providence respectively, are connected by the single main line *Q Q*. The line is divided into six circuits, which we will call respectively Nos. 1, 2, 3, 4, 5 and 6. For the purpose of rendering the connections clearer, these six circuits have been separately represented with the synchronized distributing instruments connected therewith. It will of course be understood that but a single main line *Q Q*, furnished with but two distributing instruments, viz., one *A* at Boston, and the other *B* at Providence, exists between the two cities.

This being premised, an inspection of the drawing will show that the main battery *M B*, at Boston, split and grounded at *X*, is connected with the No. 1, No. 3 and No. 5 transmitters, which are respectively connected with the No. 1, No. 3 and No. 5 sextuplex circuits of the single main line *Q Q*. At Providence the main battery *M' B'*, split and grounded at *Z*, is connected with the No. 2, No. 4 and No. 6 transmitters, which are respectively connected with the No. 2, No. 4 and No. 6 sextuplex circuits of the single main line *Q Q*.

At Providence, the No. 1 receiving relay is connected with the transmitter of No. 2 circuit, so that a message sent from Boston by No. 1 transmitter would be received by the No. 1 receiving relay at Providence, when, by means of the local battery *L B*, would have its message repeated by No. 2 transmitter, and sent to Boston over the No. 2 sextuplex circuit of the main line *Q Q*. This message would be received in Boston by the No. 2 receiving relay, when, by means of the local battery *L B*, connected with No. 2 receiving relay, would have its message automatically repeated by the No. 3 transmitting instrument at Boston, over the No. 3 sextuplex circuit of the main line circuit *Q Q* to Providence, at which place it would be received by the No. 3 receiving relay. This relay, in its turn, through the aid of the local battery connected with it, automatically transmits the message through the No. 4 transmitter, over the No. 4 sextuplex circuit of the main line *Q Q*, to Boston, at which place it is received by the No. 4 receiving relay. This relay, in its turn, through the local battery *L B* connected therewith, automatically repeats the message to the No. 5 transmitting instrument, over the No. 5 sextuplex circuit of the main line *Q Q*, to Providence, where it is received by the No. 5 receiving relay. Finally, this relay, in its turn, through the intervention of the local battery *L B* connected therewith, automatically repeats the message to No. 6 transmitter, over the No. 6 circuit to Boston, at which place it is received by the No. 6 receiving relay, by the operator stationed at the Morse instrument connected with that relay. This receiving relay is, in reality, shown in the drawing as connected with No. 1 transmitting instrument at Boston. The purposes secured by means of this connection will be hereafter explained.

Briefly, the course taken by the message in its journeys to and from the two cities, is as follows, viz.:

From Boston, by No. 1 transmitter over main line to No. 1 receiving relay at Providence.

From Providence, automatically repeated to No. 2 transmitter, and sent over main line through No. 2 sextuplex circuit to No. 2 receiving relay at Boston.

From Boston, automatically repeated to No. 3 transmitter, and sent over main line through No. 3 sextuplex circuit to No. 3 receiving relay at Providence.

From Providence, automatically repeated to No. 4 transmitter, and sent over main line through No. 4 sextuplex circuit to No. 4 receiving relay at Boston.

From Boston, automatically repeated to No. 5 transmitter, and sent over main line through No. 5 sextuplex circuit to No. 5 receiving relay at Providence.

Finally, from Providence, automatically repeated to No. 6 transmitter, over the main line through No. 6 sextuplex circuit, to the No. 6 receiving instrument at Boston, where it is received by the operator.

It is not necessary, as might be supposed from the drawing, that the characters received on the group of segments comprising No. 1 circuit must necessarily begin to return on the next adjoining segment of No. 2 circuit. Suppose, for example, that a character concluded on the segments of No. 1 circuit, where the trailing contact indicates on the drawing. By the time the armature of the relay has

[EDISO]N'S LATEST IDEAS.

Experiments for Telegraphing Between Ships at Sea.

It was rather a weird experience, meeting him. There are but two men besides himself, at eight. He was chiefly engaged with his new idea of telegraphing from railroad trains in motion. This is not to be done by a cable laid along the track, on the Phelps plan by throwing the electric current, by induction, to one of the wires alongside the railroad. His experiments have already shown that the sparks can be thrown 180 feet. The regular Morse instrument, with certain appliances, will be used. The battery is to be grounded in the wheels of the car, and on the top of the car there will be condensers, of tin foil spread upon long strips of wood. Arrangements are also progressing for an experiment in telegraphing by the same method from one ship to another at sea.

"But is that possible?" I asked. "How far do you think you can throw the current over the water?"

"I am not afraid to say how far," was the answer. "From the data already obtained, the theoretical conclusion is that we can throw it twenty-four miles. Possibly we can throw it more than that."

Then Edison sketched on paper a map of the two continents and the Atlantic, and illustrated his plan of telegraphing from ship to ship so as to establish certain communication between the shore and any part of the frequented seas. Not content with this projected miracle, which seems to be near its fulfillment, he is also busy upon improvements in submarine telegraphy. The method now generally in vogue of reckoning words through cable by the flicker of a flame thrown upon a mirror is amazingly insufficient, as is shown on a diagram which Edison displayed. The number of dots indicating letters often has to be judged by operators from the length of time that the flame hesitates. Even the siphon receiver, invented by Sir William Thompson, and used by one or two of the new cables, is not quite satisfactory, although it marks the dots pretty nearly. Edison is trying to devise some means of attaining a higher or better regulated rate of speed so that the record may be made clearer. But "its a tough job," he says.

Perhaps the most interesting thing he had to say was respecting his exploration for a "new force." At present he calls it simply x y z. He does not pretend to know what it is. But he says that there are many phenomena which are not explained by any force yet recognized, and it is these which he is going to investigate. Vibrations of matter at the rate of 30.000 a second produce the highest sound we can hear. Between these and the vibrations which, at the rate of millions per second, cause the sensation of heat, there is a large gap; and between these and the vibrations that give sensations of color there is another gap. These gaps, Edison believes, are filled by vibrations as yet unmeasured, which constitute the new, or unnamed, force he is in search of. He brought out from a drawer sundry loose sheets on which he had sketched a num-

moved in response to this character, and has placed No. 3 circuit in connection with the battery for return transmission, the trailing contact may be on the second or third contact of the No. 2 circuit. This, however, will make no difference, since both the distributing arms are synchronous so long as the rotating arms pass over two or three of the No. 3 segments, while the armature of the transmitting magnet is in contact with either of the poles of the battery.

When we consider that a message made up of many words, each word containing numerous letters, each letter consisting of numerous separate and distinct characters, and each character, under the synchronous-multiplex system, consisting of numerous impulses, was transmitted with certainty over a single wire, back and forth, this number of times, without the slightest interruption the one with the other, the fact almost challenges belief.

While these results may appear almost incredible, what I am about to describe may at first thought seem impossible. I will endeavor, however, to give such a description of this experiment, as I saw it actually made, as will persuade the reader that, so far from being impossible, its possibility must necessarily follow as a natural result of the exquisitely maintained synchronism secured by Mr. Delany's ingenious inventions.

After having successfully established by actual trial, the possibility of the use of repeaters in his synchronous system, Mr. Delany connected the relay of the sixth circuit in Boston, where the message was received, with the transmitting instrument on No. 1 circuit. Now, under these conditions, on making one dot on No. 1 instrument this dot started on its zigzag way to and from Providence, in the manner already described, only, instead of terminating on the sixth circuit in Boston, as in the previous experiment, the same dot was automatically transmitted into the first circuit, and again sent on its journeying between the two cities, only on its arrival at the sixth circuit, in Boston, to be again automatically retransmitted over this same winding route.

An inspection of the drawing will render this connection clearer. Instead of the message being received by an operator stationed at No. 6 receiving relay at Boston, this instrument is furnished with a local battery *L B*, and connected by means of the conducting wire *z z* and *z' z'* with the No. 1 transmitting instrument at Boston. By this means, therefore, the operator at the No. 6 receiving relay is dispensed with, since this receiving relay again automatically sends the signal, by means of the No. 1 transmitting instrument, on its zig-zag way between the two cities until the No. 6 transmitter at Providence again sends it to the No. 6 receiving relay at Boston which again automatically repeats it by the No. 1 transmitter, over the six circuits between the two cities, and so on indefinitely.

In this manner, then, the original signal kept passing from city to city over the different circuits in perfect rotation, without the intervention of any operator save the one who first started the signal on its ceaseless journeyings.

Timing the intervals of the returns of the original signal between the two cities over the sextuplex circuits, it was observed that it traveled between Boston and Providence over these six circuits 300 times, or covered the distance between Boston and Providence 1,800 times in each minute, thus making an entire distance of 1,500 miles a second, or 90,000 miles a minute; or for five minutes that a dot was kept going, the original signal in that short time traveled no less than 450,000 miles, or eighteen times as far as the entire distance around the world at the equator.

Of course it will be understood that most of this time was taken up by the automatic movements of the armatures of the receiving relays, and the levers of the transmitting instruments. The experimental figures so obtained, however, furnish interesting data as to the rapidity, precision and certainty with which these masses of matter may be influenced by the electric current.

An observer, noticing the progress of this experiment and reflecting on the numerous complex conditions requisite for its successful accomplishment, cannot but be singularly impressed by its extreme weirdness. Bearing in mind the exceeding complexity of structure of the synchronous-multiplex message, and the necessity for maintaining practically absolute synchronism between the distributing and receiving instruments at each end of the main line, a feeling of incredulity almost unconsciously arises in the listener's mind. Surely this weird traveler must miss some of his numerous connections; and once missed, his journeys are at an end forever. But when the signals are heard recurring with their automatic regularity, as though tossed to and fro between the cities by a mighty juggler; when they are heard as mysterious whisperings in the air, that follow too rapidly on one another to permit more than a part to be intelligently received, we almost lose sight of the actual conditions of the experiment, and begin to vaguely doubt whether Mr. Delany has not received a visit from Puck, who is bewildered by the rapidity with which he is forced to travel; and when the strange repetitions of the original signal follow one another with such rapidity and regularity as to produce a kind of a prolonged but mysterious murmur, we are almost disposed to believe that these sounds are the plaints of the Wandering Jew as he ceaselessly speeds on his never-ending journey.

Arrival of Sir William Thomson.

Sir William Thomson, the great English scientist, arrived here on the steamer Servia on the 18th ult. He is well known by repute and by his writings to all our readers. His main contributions to science have been made between 1850 and the present time. They consist of papers on "The Distribution of Electricity in Spherical Conductors," "Electro-dynamic Properties of Heat," "Thermal Effects of Fluids in Motion," "Mathematical Theory of Electricity," "Rigidity of the Earth," "Determination of a Ship's Place at Sea from Observations of Altitudes," "Approach Caused by Vibration," and on other scientific subjects. He is also the inventor of the mirror galvanometer and the siphon recorder.

In 1866, on the completion of the Atlantic cable, he was knighted and presented with the freedom of the city of Glasgow. The universities of Glasgow, Dublin, Cambridge, Edinburgh and Oxford subsequently conferred upon him the honorary degree of Doctor of Laws. He is also a fellow of the royal societies of London and Edinburgh, and received from the former the royal medal and from the latter the Keith prize. In 1871 he was President of the British Association, which met in Edinburgh, and in 1873 of the Geological Society, which met in Glasgow. In 1877 he was appointed Foreign Associate by the Paris Academy of Sciences, and in 1881 presided over the meeting of the mathematical and physical sections held in York. The latest appointment held by him was that of British Commissioner for the Electrical Exhibition held at Vienna in 1883. He was in this country in 1876.

Sir William's visit to this country is for the purpose of attending the Congress of Electricians, which will be held this month at Philadelphia. At present he is in Montreal with the British Association.

The subjoined is part of an interview with Sir William Thomson:

"Has it ever struck you, Sir William, that it would be advisable to have distinct professorships of electricity and magnetism established in the leading schools and universities?"

"That is a good idea, sir; and it might well be carried out as far as possible. Some universities have such a professorship, but not all. To lecture fittingly on electricity and magnetism a man should be thoroughly grounded in most of the other sciences, and that is the reason, I presume, why a single professor is sometimes required to give instruction on all the modern sciences. The world, however, is rapidly recognizing the fact that most of the great modern inventions are due to electricity, and that it is going to be 'the science of the future,' and it is certain that every year its study will be more insisted on by all nations."

"How long do you intend to remain here, Sir William?"

"Until November. I go to Montreal at the close of this month to preside over the mathematical section of the British Association. My main duties will be to introduce Lord Rayleigh, who has been appointed president of the association, and to deliver an address entitled 'Step Toward a Kinetic Theory of Matter.' The choice of Lord Rayleigh as president is very significant, as he is by far the ablest mathematician in England. By a 'kinetic theory of matter' I mean a theory which maintains that all the properties of matter are merely attributes of motion. After leaving Montreal I go to Johns Hopkins University to deliver a course of lectures on higher physical mathematics. After that I keep a few other engagements and return home in November to resume work at the University of Glasgow."

"What scientific work are you engaged in at present?"

"I am inventing some measuring instruments which ought to be of some practical use. I am also engaged in reprinting my lectures. The most curious, though not, perhaps, the most important, of my inventions, is the siphon recorder, which has worked something of a revolution in telegraphy."

Postal Telegraphs.—Mr. D. H. Bates, Executive Manager, and Charles Selden, Superintendent of the United Telegraph Lines, and Capt. Whitney, of the Western Union Company, had a long conference at Washington, on the 20th, with Postmaster-General Gresham, relative to fixing the rates for Government telegraph service. During the discussion of the question, the fact was developed that the rates charged by the Western Union Company were 100 per cent. greater than those offered by the United Telegraph lines. The Postmaster General displayed great interest in the subject, and closely questioned the representatives of the rival interests.

Another Change of Front.—A dispatch from Milwaukee of Aug. 27 says: "It is reported in business circles this afternoon that the Western Union Telegraph Company had purchased the lines lately [illegible] between Chicago and Milwaukee and Madison and Minneapolis [illegible] for the Bankers and Merchants' Telegraph Company. Considerable color was given to the report by the arrival here by special train from Chicago shortly before 1 o'clock of several prominent officials of the Western Union. The party included Col. R. C. Clowry, of Chicago, General Superintendent of the Western Division [illegible] of the Western Union; M. C. Bristol, of Chicago, General Superintendent of Construction; Frederick Tubbs, of Chicago, Superintendent of the First District, and E. P. Wright, of Cleveland [illegible]. The gentlemen interviewed would neither deny nor affirm the report. The purchase has undoubtedly been made, and it is rumored that the Western Union will own the entire system of the new company before many days.

The Providence Clam Bake.

In August, 1879, Mr. Eugene F. Phillips invited a few of his friends and customers to Providence, to partake of a genuine Rhode Island Clam Bake with him. There were only a few in the party, but they enjoyed themselves so well and had such a general good time, that a similar dinner has been given every year since. As nobody has yet been found who, having attended one of Mr. Phillips' clam dinners, would willingly stay away from another, it of course goes without saying that each succeeding bake has been more largely attended than its predecessor.

At the sixth of these occasions, which was held on Wednesday of the present week, the guests numbered more than a hundred. They came from all sections of the country, even as far as the Pacific Slope. In years gone by we were able to give a pretty complete record of those present, but the list this time is so formidable and the columns of The Operator are so crowded that we must be content to say that every large town or city with a telephone exchange or an electric light station seems to have sent a delegate.

The bake was held on the grounds of the Vue d'Eau Club, about five miles from Providence. These were reached by boat after a brief sail down the Narragansett. The time before luncheon and between luncheon and dinner was principally devoted, as usual, to various kinds of outdoor sports, though some sat in the shade enjoying the beautiful scenery or watching the steamers and sailing craft going up and down the river, while others renewed pleasant acquaintances of former years.

At three o'clock the bake was opened, after a brief address of welcome by Mr. Phillips and the Rhode Island Secretary of State. The bill of fare was got up in an exceedingly neat and tasteful manner, while the badge which each guest was supplied with was particularly handsome. It was of white silk, and bore in blue letters the legend "The Sixth Annual Bake. Complimentary to Telephone, Telegraph and Electric Light Men. Tendered by American Electrical Works. E. F. Phillips, President. Providence, R. I.; 1884." This was fastened at the top to a piece of copper wire rope, from which depended a miniature telephone cord. The dinner consisted of half a dozen courses, and there can be no doubt about every one enjoying it. During the meal one of the waiters inquired if there was a Mr. Merriman present. "Merry man!" replied Mr. Stephen D. Field, "can't you see that we are all merry men?"

We were much interested in learning from Mr. Phillips something about the origin and development of the electrical wire department of his business. It was in 1870 that he first began covering wire. He had previously been manufacturing gas tubing, and is still, we believe, the only manufacturer of that commodity in this country. A Providence man not connected with the electrical business, but who saw there was a demand for something of the kind, suggested to Mr. Phillips that he should cover some wire and send it to the Gold & Stock Telegraph Co. of New York. The first he made very much resembled in appearance a wire coated with sleet or snow, and the paraffine was in the habit of peeling off in flakes. Still, there was a market for it, and later on the surface was made much smoother by pressing, and subsequently came in vogue the patent finish which renders the office wire of to-day such a thing of beauty.

There was but little business done in covered wires until 1878, when the District companies were started. The greatest development, however, came with the introduction of the telephone, and the business advanced still more with the advent of the electric light. It will probably surprise even electricians to know that this one concern now turns out almost a ton of electrical wire every working day. We asked Mr. Phillips for an estimate of his product, and after reckoning up he gave it as being about 300 tons a year. When it is remembered how many other manufacturers of covered wire there are in this country, some idea may be formed of the importance of this industry.

Telegraph Instruments in France.—*L'Electricité* says that there are at the present time 7,703 Morse instruments at work in France. The Baudot apparatus, which works between Paris and Marseilles, transmits 1,800 messages per diem.

Beecher Portable Telephone.—Capt. Beecher had an interview with army officers during the week as to experiments with his portable telephone, and will visit them next Monday, for the purpose of making arrangements for its use by them. A great deal of interest is being shown in the invention by both branches of the service.

Operations in New Jersey.—The Philadelphia & Seaboard Telegraph Company laid a second cable between Philadelphia and Camden on the 20th containing ten copper conductors. The Clay Commercial Telephone Company will employ some of these wires in connecting their exchanges between the two cities. The officers of the Philadelphia & Seaboard Company are as follows: William G. Perry, No. 728 Arch street, President; Henry C. Terry, 110 South Third street, Vice-President and Solicitor; C. A. Wilson, of Luzerne Oil Refinery, Treasurer; J. E. Gill, banker, Second Vice-President; John J. Burleigh, Secretary; Heber C. Robinson, General Manager. The above gentlemen, including Mr. Charles M. Burns, are Directors. The Company own and control the underground, submarine and aerial cables invented by George B. Pennock, the General Superintendent of the Company. The Reading Railroad are using one of these underground cables, and pronounce it a perfect success.

84

moved in response to this character, and has placed No. 2 circuit in connection with the battery for return transmission, the trailing contact may be on the second or third contact of the No. 2 circuit. This, however, will make no difference, since both the distributing arms are synchronous so long as the rotating arms pass over two or three of the No. 2 segments, while the armature of the transmitting magnet is in contact with either of the poles of the battery.

When we consider that a message made up of many words, each word containing numerous letters, each letter consisting of numerous separate and distinct characters, and each character, under the synchronous-multiplex system, consisting of numerous impulses, was transmitted with certainty over a single wire, back and forth, this number of times, without the slightest interruption the one with the other, the fact almost challenges belief.

While these results may appear almost incredible, what I am about to describe may at first thought seem impossible. I will endeavor, however, to give such a description of this experiment, as I saw it actually made, as will persuade the reader that, so far from being impossible, its possibility must necessarily follow as a natural result of the exquisitely maintained synchronism secured by Mr. Delany's ingenious inventions.

After having successfully established by actual trial, the possibility of the use of repeaters in his synchronous system, Mr. Delany connected the relay of the sixth circuit in Boston, where the message was received, with the transmitting instrument on No. 1 circuit. Now, under these conditions, on making one dot on No. 1 instrument this dot started on its zigzag way to and from Providence, in the manner already described, only, instead of terminating on the sixth circuit in Boston, as in the previous experiment, the same dot was automatically transmitted into the first circuit, and again sent on its journeying between the two cities, only on its arrival at the sixth circuit, in Boston, to be again automatically retransmitted over this same winding route.

An inspection of the drawing will render this connection clearer. Instead of the message being received by an operator stationed at No. 6 receiving relay at Boston, this instrument is furnished with a local battery *L B*, and connected by means of the conducting wire $x\ x$ and $x'\ x'$ with the No. 1 transmitting instrument at Boston. By this means, therefore, the operator at the No. 6 receiving relay is dispensed with, since this receiving relay again automatically sends the signal, by means of the No. 1 transmitting instrument, on its zig-zag way between the two cities until the No. 6 transmitter at Providence again sends it to the No. 6 receiving relay at Boston which again automatically repeats it by the No. 1, transmitter, over the six circuits between the two cities, and so on indefinitely.

In this manner, then, the original signal kept passing from city to city over the different circuits in perfect rotation, without the intervention of any operator save the one who first started the signal on its ceaseless journeyings.

Timing the intervals of the returns of the original signal between the two cities over the sextuplex circuits, it was observed that it traveled between Boston and Providence over these six circuits 300 times, or covered the

THE Port Morris branch of the New York & New Haven Railroad have perfected a system of telegraphing by which messages can be sent and received on a running train. Mr. Lucius J. Phelps is the inventor. The present system extends twelve miles, but it is expected to extend it to the main line.

THOMAS EDISON is now experimenting with an invention of his, designed to prevent collisions by railroad trains. The new device is intended to permit engineers of trains to communicate easily with one another when the trains are a mile apart and in motion. The medium of communication is the telegraph wires along the railroad and an instrument in the engineer's cab. This instrument resembles the telephone in some respects. It is to be hoped that Mr. Edison will succeed in this humanitarian undertaking.

...N'S LATEST IDEAS.

Experiments for Telegraphing Between Ships at Sea.

It was rather a weird experience, meeting him. There are but two men besides himself, at night. He was chiefly engaged with his new idea of telegraphing from railroad trains in motion. This is not to be done by a cable laid along the track, on the Phelps plan by throwing the electric current, by induction, to one of the wires alongside the railroad. His experiments have already shown that the sparks can be thrown 180 feet. The regular Morse instrument, with certain appliances, will be used. The battery is to be grounded in the wheels of the car, and on the top of the car there will be condensers, of tin foil spread upon long strips of wood. Arrangements are also progressing for an experiment in telegraphing by the same method from one ship to another at sea.

"But is that possible?" I asked. "How far do you think you can throw the current over the water?"

"I am afraid to say how far," was the answer. "From the data already obtained, the theoretical conclusion is that we can throw it twenty-four miles. Possibly we can throw it more than that."

Then Edison sketched on paper a map of the two continents and the Atlantic, and illustrated his plan of telegraphing from ship to ship so as to establish certain communication between the shore and any part of the frequented seas. Not content with this projected miracle, which seems to be near its fulfillment, he is also busy upon improvements in submarine telegraphy. The method now generally in vogue of reckoning words through cable by the flicker of a flame thrown upon a mirror is amazingly insufficient, as is shown on a diagram which Edison displayed. The number of dots indicating letters often has to be judged by operators from the length of time that the flame hesitates. Even the siphon receiver, invented by Sir William Thompson, and used by one or two of the new cables, is not quite satisfactory, although it marks the dots pretty nearly. Edison is trying to devise some means of attaining a higher or better regulated rate of speed so that the record may be made clearer. But "Its a tough job," he says.

Perhaps the most interesting thing he had to say was respecting his exploration for a "new force." At present he calls it simply x y z. He does not pretend to know what it is. But he says that there are many phenomena which are not explained by any force yet recognized, and it is these which he is going to investigate. Vibrations of matter at the rate of 30.000 a second produce the highest sound we can hear. Between these and the vibrations which, at the rate of millions per second, cause the sensation of heat, there is a large gap; and between these and the vibrations that give sensations of color there is another gap. These gaps, Edison believes, are filled by vibrations as yet unmeasured, which constitute the new, or unnamed, force he is in search of. He brought out from a drawer sundry loose sheets on which he had sketched a num-

ber of machines he had projected, which respond to some influence still undefined. "I jot these down as they occur to me," he said, "and when I get enough of them together I shall have the machines made and try to generalize my observations."

Think of it! A man in this skeptical century who dares to believe in a discovery beyond all discoveries. Here is student of nature who is not afraid to have the spirit of a Galileo or a Keppler or an Isaac Newton. Perhaps we shall learn from him that in returning to faith and insight, aided by bold and patient experiment, we may go forward by going backward. "What do you think as to the nature of matter?" I asked, unscrupulously. The answer was prompt: "I do not believe that matter is spirit, acted upon by an outside force. To me it seems that every atom is possessed of a certain amount of primitive intelligence. Look at the thousand ways in which atoms of hydrogen combine with those of other elements, forming the most diverse substances. Do you mean to say that they do this without intelligence? When they get together in certain forms they make animals of the lower orders. Finally, they combine in man, who represents the total intelligence of all the atoms."

"But where does this intelligence come from originally?"

"From some power greater than ourselves."

"Do you then believe in an intelligent Creator, a personal God?" was the next question.

"Certainly," said Mr. Edison. "The existence of such a God, in my mind, can almost be proved from chemistry."

Lucretius thought that all atoms were moved by feelings of love or hate—what we call attraction or repulsion. Edison's idea is far more subtle, since he allows the atoms only a germ of intelligence. It also seems to be quite in keeping with the doctrine of evolution, while it contains nothing that is not in harmony with the idealism of the Platonists. And so we discover down on Avenue B, in the prosaic city of New York, a philosopher who believes in a personal God, and is at the same time the foremost exponent of applied science. Curious that he should be at work here, night after night, in the midst of a million of people, only a few hundred of whom know how he is employed during the nocturnal hours. As a usual thing he works until 5 or 7 o'clock in the morning, his supper basket remaining untouched beside him, and sometimes it is 9 o'clock of the next day before he leaves the bench of the laboratory. "I can't think out anything," he says "except when I'm experimenting. I have a library of 7000 scientific works, but somehow I can't find what I want in books. How do I make calculations? Well, I don't know exactly. I can't do it on paper. I have to be moving around."

So there he goes, moving around, thinking and working with his hands, in the big, sombre building, while the city is asleep. He is the controlling power of several large factories, a millionaire, a man of business, a marvelous inventor; yet he is as simple and happy as a child; when wrapped in an old seersucker dressing gown, he can manipulate at will and without interruption, the mysterious forces and properties of nature. In meeting him I thought of him more as a poet or a musician than as a machinist and electrician. Like the Brahmin I saw last week, he deals with occult powers, in quite a different way, but perhaps to the same end of perfecting man's control over the elements that shape life. It was significant that we climbed a dark stairway to reach his topmost place of light and intelligence. Americans are practical and skeptical. It ought to amuse them greatly to learn that the champion of their inventive genius is largely a be-

Thomas A. Edison, says the New York *Tribune*, is experimenting on Erastus Wiman's Staten Island Railroad, with what he calls "Grasshopper electricity." He proposes to telegraph from one moving train to another moving train. The system is similar in some respects to the Phelps induction telegraph, but unlike it in that Mr. Edison proposes to use the rails of the road as the means of conducting the current of electricity. He "jumps" it from one rail to the next; hence the peculiar name which he has given it. Mr. Edison has also made an important discovery and contrived an improvement on his quadruplex telegraph. His quadruplex machine enables him to send simultaneously several messages over a single wire provided all started from the same point. The improvement enables an operator at any station to break in at any time and have a portion of the wire for his particular current. Mr. Edison asks the Western Union $10 a year for each station as a royalty on the patent he has already secured.

The New Magneto Telegraph.

[From the Fort Worth Gazette.]

The new magneto telegraph and telephone instrument, a description of which is given below, was invented by Mr. F. H. Brown of this city. Mr. Brown has been working on this invention for some time, and perfected it in February last. The test that he made of the instrument at that time proved satisfactory, so he at once secured a patent, and made another public test about a week ago between Fort Worth and Cleburne. This test was made at the request of stockholders in the Holt and Baxter Telephone and the Western Union Telegraph Companies, and also proved perfectly satisfactory.

This invention is certainly a wonderful thing and threatens to revolutionize the whole system of telephoning and telegraphing. In one of his tests Mr. Brown attached his instrument to the telephone wires here and talked with perfect ease and distinctness to Decatur. Mr. Brown has already disposed of interests in his invention in nearly all foreign countries.

Ever since the days telegraphy by batteries commenced scientific men have been striving in vain to telegraph without battery currents. During wars this was very desirable to aid

The Purcelle System of Multiple Telegraphy.

A new system of multiple telegraphy, based on the invention of Mr. Albert L. Purcelle, of Boston, has recently attracted much attention from electricians and telegraph men. While using the two arms revolving in unison over two circular tables of contacts at the two ends of the line, as has been done in the attempts to accomplish multiple telegraphy, the other features of this system are said to be so radically new as to be of considerable public interest in view of the end aimed at.

The essential points in a multiple telegraph system are, first, to provide two motors capable of running very closely together and thus keeping the revolving arms at the two stations very nearly in unison; and, secondly, to provide an absolutely reliable means of correcting the arms when one gets ahead of the other and bringing them into unison again. The first point is gained by using as the motors for the two arms two strips of brass, called reeds, with armatures on the end, driven electrically; two reeds of exactly the same dimensions, as is well known, will have exactly the same rate of vibration and will, therefore, keep time with each other regardless of the amount of current used. Heretofore, reeds have been used merely as circuit breakers; but, in this system, they are driven in an entirely novel manner, which makes it possible to drive the revolving arm by direct mechanical action from the reed by means of an anchor lever and ratchet wheel. The next point, after securing approximate uniformity in the movement of the arms, is to provide for correcting them when the slight variations which are inevitable occur. The advantage claimed is that it accomplishes this by a positive movement that cannot fail. When one arm is in advance of the other it abuts against a detent lying in its path; this forms a circuit which holds the reed firmly at one end of its swing, where it remains until the other arm catches up, when it is released and starts off again at its regular rate of vibration, this process being repeated as often as necessary.

The work of building the machine has thus far been carried on in New York City under the direction of the National Electric Company, formed here to control the inventions for the United States; but a new company has just been organized to work the inventions in Europe, having on its board of directors a number of well-known Boston men; and work for that company also is now being carried forward.

The inventions have many important applications besides the multiple telegraph. The extension of long-distance telephony makes them, it is thought, of much importance in the telephonic field. The method of driving a reed has been applied also with great success to the pendulum of a clock, thus dispensing entirely with the spring and train and making, it is claimed, a time-piece of great simplicity, cheapness and accuracy, run locally by a single cell of gravity battery. A clock has been completed and has been exhibited in successful operation here for several months, where it has attracted much notice. These inventions cover likewise new forms of printing telegraphs and stock reporters, said to be simple and cheaper of construction and more reliable in operation than any yet devised.

The names subjoined show the character and standing of persons composing the company: President, William F. Drake, Supt. N. Y. Stock Exchange; Vice-President, Henry E. Alexander, Latham, Alexander & Co.; Treasurer, Charles C. Allen, Member N. Y. Stock Exchange. The above, with Josiah Quincy, attorney-at-law, Boston, and Albert A. Drake, member N. Y. Stock Exchange, constitute the full board of directors.

"What's a 'phonoplex'?" I inquired as that strange word was buzzed about my ears the other day in a company of electricians. "It is the latest telegraphic device—Edison's," explained A. O. Tate. "Its effect is to make a single wire do double duty. But it is nothing like the duplex, which can be worked from terminals only. The phonoplex enables us to work on a wire already in use for despatches, and we can telegraph either way on it and chip in anywhere along the line. We use static electricity, the same as in the air-telegraph, but substitute a metallic diaphragm for the Morse sounder. Two lines are already phonoplexed in this city, and the new wrinkle has been added to the Montreal and Toronto line."

"We are rather scared about Edison," said one of his recent electrical associates to me the other day. In reply to questions, he continued: "We haven't heard a word from him. It is three weeks now since he married that Buckeye girl and he has taken no notice whatever of us in all that time. We have written to him. We have telegraphed him. We get no response. He has cut us dead. We ask him questions requiring immediate attention and that is the last of it. We are running the concern without him. He ignores the telegraph and despises the mail. It doesn't look as if his young wife had a rival in science or was being neglected for any new-fangled contrivance, does it? If we don't hear from him pretty soon we shall send an ambassador down there or a thoroughly equipped committee." W. A. CROFFUT.

MR. EDISON'S "Phonoplex," or "Way Duplex," which we describe in another column, is a most ingenious application of the varying action of the telephone when subjected to currents of different qualities. It is somewhat strange that the telephone has not been more generally introduced into railroad service, but this new adaptation of it is one step in the right direction. The entire independence of the operation of both kinds of signals from the condition of the line, evidently makes it possible to send and receive from any point without altering the condition of any of the office apparatus. The system is specially adapted to railroad work where a large number of offices are looped in on the same line, and where heretofore only one could be communicated with at a time. The application of the telephone to the purposes of a telegraph sounder, the loudness of which exceeds even that of the ordinary "giant" sounder, is destined to a wider application than would appear at first sight. Such sounders being very sensitive, and that only to the momentary high-potential currents sent over the line, might with equal propriety be substituted on the ordinary single lines instead of the relay and sounder. The battery required is practically the same for all distances, and is far less than is necessary with the Morse system. Altogether the invention is a very promising one, and while not entirely original in principle, it is nevertheless a new application of considerable originality, in a department where Mr. Edison has done some of his best work.

Edison's New Harmonic Telegraph.

Thomas Edison, as inventor, and the Western Union Telegraph Company, as owners, have received letters patent on a new harmonic telegraph, a method of transmission by which two or more messages may be sent the same or different directions on the same wire. The principle involved has been known to inventors, and was experimented with by Varley and Gray. Mr. Edison applied to the department for a patent on May 15, 1877, and since then has worked intermittingly upon his invention.

QUADRUPLEX TELEGRAPHY.

The General Principle Upon Which Edison's System is Operated.

At a meeting of the Electrical society last evening A. C. Terry of the Western Union telegraph described to the electricians present the method of operating the Edison quadruplex telegraph.

The general principle, Mr. Terry said, upon which the system is worked is based upon the fact that two sets of signals can be sent in the same direction over one wire by combining reverse currents and a single current working in such a manner as to cause one receiving instrument to be operated by the reversal of currents only, irrespective of their strength, whilst another instrument will respond to changes only in the strength of the current regardless of its polarity. This method of double transmission in the same direction is known as diplex telegraphy. By combining this with the duplex, Mr. Edison, in the year 1874, gave to the world the quadruplex system of telegraphy which has since come into such general use in the United States and Europe.

Hereafter the society will hold its meetings in the rooms of the Society of Natural Sciences in the Buffalo Library building, arrangements having been made whereby it becomes a branch of that society, holding the same relation to it as does the Microscopical club, the Field club and other organizations devoted to the investigation and advancement of any of the departments of physical or natural science.

Long Distance Telegraphing.

On the heels of the news of the absorption of the Baltimore and Ohio Telegraph Company by its rival, the Western Union comes some comforting information with regard to the progress made in long distance telegraphing. It is authoritatively stated that success has at last been reached by three discoveries—the manufacture of a hard-drawn copper wire of great tensile strength and high conductivity; the long-distance transmitter, an adjunct to the system which generates the electrical impulse by which the great invention of Alexander Graham Bell is operated, the result of the united labors of Blake, Edison, Berliner, Grilliand, Hughes and others; and the elimination of all inductive and disturbing influences, by the American Bell Telephone Company, who built a test line from New York to Boston, and fully demonstrated the practicability of two wires in metallic circuit, protected from ground connections.

Long distance outfits are being rapidly placed for interchange of communication between big cities and suburban places. By means of the terminal connecting lines, New York business men can be placed in immediate and direct speaking communication with any of the subscribers to the telephone exchange in Philadelphia and the cities and towns in New York, New Jersey, Connecticut, Massachusetts, and other states. Very heavy lines are now being constructed to points in New England and to Albany. The Boston circuit will be opened in three weeks, with thirty wires, and the communication will be as direct as it is now between New York and Philadelphia. It is expected that the service to Albany will be opened on January 1. The lines will be extended through the state to Buffalo, to Cleveland, to Cincinnati and to Chicago. So perfect is the system that talk can be carried on as easily between points 500 miles apart as 100 miles. Tests recently made show that such a performance is entirely practicable. There are newspaper offices in New York and Philadelphia furnished with long distance outfits, and news matter is transmitted daily. Single wires from New York to Philadelphia are now rented at $100, those to Boston will command double that price. The New York Times tells a story of a recent achievement on long distance telephoning which illustrates the uses to which it can be put. A railroad company got up a new time table, which was put in type 200 miles from the executive office there. The proof was read and corrected by copy over the telephone wire with almost as much facility as if the company's representative had been in the printer's office. Those who have watched the development of the telephone are enthusiastic over the possibilities of the long distance system, and say it is destined to work a revolution in professional and commercial circles.

Tribune, Chicago, Ill. March 25, 1888.

PROF. ELISHA GRAY'S TELAUTOGRAPH.

It Was Not Exhibited Yesterday—A Description of the Instrument.

Some three months ago THE TRIBUNE gave a description of Prof. Elisha Gray's wonderful new instrument for the transmission of handwriting. He calls it the telautograph. He was to have given a trial exhibition yesterday to a party of Eastern gentlemen, but not all of them came and the event was deferred until the first of the coming week.

The little instrument which threatens to revolutionize both the telephone and the telegraph is in its general appearance a stand or table with duplicate parts. On one of these parts are the appliances for transmitting and the other for receiving. Each is a disk covered with specially prepared paper. The operator writes on the paper as on an ordinary sheet and the message is reproduced on the connected instrument. If the adjustment is perfect the chirography will be reproduced in perfect fac-simile, just as a telephone transmits the voice. The power of the instrument is equal to that of the telegraph, and a longer range of connection is possible than with the telephone. An advantage of the instrument will be that it will facilitate commercial business, and letters which are now handled by mail can be sent over the wire with the convenience of telephone transmission.

Prof. Gray developed the instrument some time ago and applied for patents. His claims were passed upon some time ago, and the only protection he seeks now is that of the old countries.

Times-Democrat, New Orleans, La. Feby 2, 1888.

NEW SYSTEM OF TELEGRAPH.

Another Invention [illegible] a Moving [illegible]

Special to The Times-Democrat.

LAREDO, TEX., [illegible] some time past Lieut. [illegible] of Fort McIntosh, has been arranging the wire, etc., along the line of the Mexican National from the depot in this city to a point three miles distant, for the demonstration of a new mode of railway telegraph invented by himself and Capt. C. W. Williams, also of the United States army.

Yesterday afternoon the method was practically demonstrated in the presence of quite a number of gentlemen, among the number was Mr. J. N. Galbraith, assistant superintendent of the Mexican National, and is pronounced a success, proving that telegraphing to moving trains on railways will eventually come into vogue. The Ives-Williams method differs from that of Edison and Phelps in several particulars, principal among which is the doing away with the use of a telephone receiver. A strong, low tension current from a battery on the car is made to work a repeater on the ground, which retransmits the ordinary Morse signals over the main line.

The method is composed of a series of consecutive sections, each containing a repeater, and by using short sections, with a low tension current, grounding is avoided. The line conductor was a bare wire stretched along and spiked to the crossties, and though the ties and ground were both wet from recent rains, there was comparatively no grounding. The current passing through the car consists of the rails, a wire stretched parallel to the train, and means for preserving contact between this wire and the moving car.

This is done by placing at intervals of thirty feet contact surfaces, electrically connected to the line wire; on the car, stretching taut from the front to the rear a brass wire which slides on the contact surfaces as the train moves along. This brass wire is electrically connected through a battery key and relay with the truck frame. At the station a wire is carried through the repeater from the rails to the wire stretched parallel to the track. The messages transmitted to and from the car were received by ordinary Morse sounders, and this is one of the main advantages of this class of railway telegraphy.

89

Journal, Indianapolis, Ind. Nov. 26, 1888.

WHAT is Edison doing that he has allowed both American electricians to come in of him with so important a discovery as of telegraphing without a battery? The country has depended on Edison to keep the lead in such matters.

Ledger, Phila. Pa. Aug. 6, 1888.

PROF. GRAY'S TELAUTOGRAPH, with which telegraphic messages are to be sent in one's own handwriting, is said to be based on a newly-discovered electrical principle, and is also reported to work so accurately and rapidly as to give promise of being commercially successful. Several attempts have been made to devise apparatus of this kind, and Edison had so far succeeded six or eight years ago that at Menlo Park, with laboratory apparatus, autograph messages were sent with entire success, so far as the reproduction of the message at the other end of the line was concerned. It worked at a fair rate of speed, but not as rapidly as was desired. Edison's other work drew him away from this apparatus at a time when it seemed to be approaching perfection. Prof. Gray has no doubt reached the same end by other means.

Herald, Chicago, Ill. Aug. 5, 1888.

Writing Afar.

The glory of the telephone is the glory of Chicago, for we of this city heard the music coming out of Elisha Gray's empty box a year before the Bells and Edisons were thought of. It is, therefore, with feelings of especial pleasure that the success of Professor Gray's tel-autograph is assured. Once more the greatest of inventors stands before the world the admiration of nations and the ornament of the most ingenious age.

What Eastern buccaneer will undertake to patent a tel-autograph the same day Professor Gray gives up his secret to a Patent Office clerk? The plan worked well with the telephone, and there were millions in it.

Yet, since the Supreme Court stands with a Chicago man in the panel, it is doubtful if so bold a foray would succeed the second time.

Herald, Chicago, Ill. March 21, 1888.

BEATS THE TELEPHONE.

ELISHA GRAY'S LATEST INVENTION.

By the Telautograph a Man Can Escape All the Horrors of the "Hello" Machine—A New Telephone Switch Board—The Case of Gray Versus Bell.

Professor Elisha Gray, of Highland Park, has just completed an invention scarcely less wonderful and valuable than the telephone, of which he was also the inventor, but of which he was defrauded. "Within a few days," said the Professor yesterday, "I shall give a private test of my new telautograph, an invention which will largely supplant the telephone. I have already tested it to my satisfaction, over and over again, and on Saturday I shall give an exhibition to some gentlemen from the East. I have just taken it to pieces to make some slight alterations, or I would show it to you now.

"By this invention you can sit down at your office in Chicago, take a pencil in your hand, write a message to me, and as your pencil moves a pencil here in my laboratory moves simultaneously and forms the same letters and words in the same way. What you write in Chicago is instantly reproduced here in fac-simile. You may write in any language; write in shorthand if you like, use a code or cipher, no matter, a fac-simile is produced here. If you wish to draw a picture it is the same—the picture is reproduced here. The artist of your paper can, by this device, telegraph his pictures of a railway wreck or other occurrence, just as a reporter telegraphs his description in words. The two pencils move synchronously, and there is no reason why a circuit of 500 miles cannot be worked as easily as one of ten miles.

"This telautograph will supplant the telephone for many purposes. It can be worked in exchanges, just as the telephone is, or by private wire. It has many advantages, too. It is noiseless and devoid of the many annoyances so common to the telephone. It will be much less affected by induction. There will be no trouble in catching words or syllables, letters or figures. No misunderstandings will result. Besides, it leaves a record at both ends of the wire, and there can be no dispute about what was said. For all commercial transactions this would be an invaluable feature. In ordering goods, or sales of stocks or grain, or in transmitting names or addresses its superiority over the telephone is obvious. For desultory conversations, it is true, it would not be so rapid of working, for the reason that one cannot write as fast as he can talk, but, on the other hand, it would save many of the delays and annoyances incident to telephonic communication.

"When one person wishes to communicate with another by the telautograph he pushes a button, which rings an annunciator in the exchange, or in the office of the person with whom he wishes to converse. Then the first party takes his writing pencil from its holder—and this may be pen or pencil—and writes his message upon a roll of paper. As he writes so writes the pencil at the other end of the wire. Finishing his message, he adds a cross, or any other simple token that he has finished, when the second party takes down his pencil and writes a reply. Thus a conversation can be carried on easily and quickly, and when it is finished another simple word—say the telegraphic signal "30"—will indicate the end. Both parties have a full record of the conversation, and each possesses the other's autograph.

"In writing," continued the professor, "your pen or pencil is attached to two small wires, and these wires regulate the currents which control the pencil at the other end of the wire. But these wires give you no trouble. You hardly know they are there, and can write with as much facility as if they were absent."

"Can this invention be used to advantage commercially?"

"Yes. It will not cost more than $15 or $20, and is easily kept in order. I have tried it again and again, and it works more perfectly than the telephone, and is much less liable to have its usefulness interfered with by induction.

But this is not the only great invention Professor Gray has in hand. He has just completed also an automatic switch-board for telephone exchanges by which the user of a telephone or telautograph can put himself in communication with any other instrument. To do this he has simply to touch a button a certain number of times corresponding to the number of the other instrument. If the wire leading to that instrument is already in use he is informed of that fact by the ringing of a bell, and he then waits a few minutes, as he is now so often compelled to do, and then pushes the button again. By this invention one person in an exchange can do the work of thirty or forty under the present system, the duties of the one being merely to keep the automatic apparatus in order.

Herald, Chicago, Ill. March 26, 1888.

ELISHA GRAY'S PATENT

HIS CLAIM TO THE HELLO MACHINE.

A Visit to His Home and Laboratory at Highland Park—The Story of His Eventful Life—Did Bell Filch from Gray's Caveat?

Professor Elisha Gray, the inventor of the speaking telephone and the telautograph, lives in a handsome home, surrounded by walks, drives, water-courses and shrubbery, in the charming suburb of Highland Park. The Professor is a man of fifty, genial, companionable, a good talker and exceedingly modest concerning his own achievements and successes. His kindliness and generosity have made him a universal favorite among Highland Parkers, and his mastery of the most mysterious and wonderful of arts has caused him to be admired by all who know or have heard of him. The Professor is six feet tall, straight, with a rather long face, expression thoughtful, simple manners, lips which often part in smile and are seemingly incapable of giving utterance to harsh words, hair and beard plentiful and now tinged with gray, blue eyes and a complexion

PROFESSOR ELISHA GRAY.

warm and ruddy with health. His home is full of flowers; large windows let in plenty of sunshine; throughout the house are electrical toys and a diversity of ornaments made with his

own hands; in his library is a mineral collection and a great store of electrical books, and on the walls hang several medals and diplomas awarded him in this country and abroad for his great inventions, among them the decoration of the French Legion of Honor. The Professor barely mentions these, and real pride is exhibited only when he points to the portraits of his mother, his wife and of his beautiful daughters, two of whom are at Oberlin College, where their father holds the chair of electrical science.

But it is in his workshop that the Professor feels most at home and is most interesting. An electric bell at the door of a cottage in a ravine is marked: "Professor Elisha Gray—laboratory." The upper story of this cottage is filled from floor to roof with tools, drawings, strange devices, little tables, boxes, castings of brass, lathes, forges, blow-pipes, electric jars, wires and all the paraphernalia of the workshop of a master of the science of electricity. Professor Gray not only thinks but works. He is an excellent mechanic. His hands, to all appearances, are as soft and white and unblemished as a baby's, but there are callouses in their palms. Only the skillful workman can keep hands like his.

"I am afraid I could never have accomplished much," he says, "had I not been able to work to advantage with my hands. A man, in my opinion, is never fully educated or properly equipped until he knows how to use his hands as well as he does his brain. I think I had the advantage of being born a mechanic. From my earliest recollection I was profoundly interested in all the phenomena of nature, and whenever I saw any manifestation of physical force I could not rest content until I had solved the secret of its operation. Whenever I saw a piece of machinery I at once set about making one like it. As a boy I made a great number of machines, ranging from a saw-mill run by water power to a Morse telegraphic apparatus. From the first electricity had a wonderful charm for me. I read everything I could get hold of on this subject, and spent so much time with my reading and experimenting that my parents used to scold me and try to convince me that I was wasting opportunities to learn something useful. Of course I couldn't blame my mother. It was not pleasant for her to find that whole skeins of flaxen thread, which she had spun with her own fingers, had been used up in making belts to run a boy's toy machinery, or to discover that her best clothes had been notched into saw teeth with which to equip a miniature saw-mill. I couldn't blame mother for scolding when she found her only quart bottle—quart bottles were scarce in those days—converted into a cylinder for an electrical machine, or when she saw that the copper bottom of her wash boiler had been cut up to make the plates of a galvanic pile. I even believe I would have invaded the sacred precincts of mother's band-box, which was only opened once a week, if I could have found anything there useful in my experiments."

Professor Gray's parents saw that he was a mechanic, but as they had no dreams of the possibilities which the future offered for his devices, they apprenticed him to a blacksmith. But that work was too laborious. The youth had not a very strong body, and he says he never knew how to hold up a horse's leg without any satisfaction to himself or to the horse. That was at Barnesville, Ohio, where he was born in the year 1835. Later on his parents removed to Brownsville, Pa., and Elisha there served a full apprenticeship as a carpenter, joiner, and boat-builder on steamboats designed for the Mississippi trade.

All this time he was restless and dissatisfied. There was a new world of which he had had a glimpse, and which he longed to enter and explore. He wanted knowledge. His evenings were spent in study, and after serving his apprenticeship of four years as a journeyman car-penter he went to Oberlin College, paying his expenses there by working off days and vacations at a carpenter's bench. While his classmates studied natural philosophy by book and theory he with his own hands constructed and carried into class such simple apparatus as would best illustrate the principles under consideration. Of course a man like this must become an inventor. It has been said that inventors, like poets, are born, not made. But Elisha Gray could not have mastered the mysteries of electricity and produced a telephone and a telautograph had he not possessed courage, industry, will and spirit. He became a great inventor by first becoming a master of the science and then working toward which his boyish inclination led him. For six or seven years after leaving college he was an invalid, practically unable to continue his labors, but his mind was constantly active, and almost immediately began that long series of discoveries and applications in electricity, of which, happily, the end has not yet been reached. His first patent was taken out in 1867, and since that time forty patents have issued in this country on electrical devices of his, and half as many in foreign countries. Numerous valuable devices have not been patented, and from them all the Professor derives but a comfortable income. He began work in Cleveland, Ohio, being connected with the Western Union shops there, but came to Chicago fifteen years ago and became president of the Western Electric Company, a concern which made more money out of his inventions than he did. An earnest and enthusiastic delver in the magic mines of electricity and magnetism, he cared little for business success. He got himself and his financial interests, and sometimes neglected his meals and his bed. Various electrical appliances for telegraphy, among them telegraph repeaters, dial telegraph instruments, multiplex telegraphy, a telegraphic printer, which was extensively employed by the Gold and Stock Exchange Telegraph Company, a telegraph switch and various forms of electric annunciators now in general use, came rapidly forth as the products of his busy brain and hand. Had he received even a small royalty on these devices he would now be a very wealthy man, and had he not cleared legs for art and more for self A. Graham Bell would not now be enjoying the millions which the telephone has brought him.

rapidly at the sending end and a pair of electro magnets at the receiving end. The sender uses either a pen or pencil, near the point of which are attached two threads running at right angles to each other, and each one passes in a current interrupter moved to the right too sorrowful [illegible] ... The telautograph, as Mr. Gray calls his invention,

therefore not only insures accuracy, but is exactly copies the sender's handwriting as to hold him accountable for what he has written, while he retains for his own guidance the original of the message transmitted. The experiments made show that there is no difference to the handwriting at the two ends of the wire except that which is incident to the use of a stylographic pen at the receiving end.

N. Y. Herald, Dec. 16, 1888.

WRITING SENT BY TELEGRAPH.

ELISHA GRAY'S INVENTION FOR SENDING FAC-SIMILE [illegible] BY WIRE.

Electricity is the good genius of this century. Those who know most about it say that what we have done with it in the past is but a trifle compared with what we may hope to do with it in the future. There are people who expect some day to be able to call a distant friend by wire, see his image in a mirror, hear his voice, and, if desired, get his exact signature to a subscription paper or a check.

These things may all come. At present we get tion of the voice over the wire, having no means of determining the identity of our interlocutor, no certainty of getting his words accurately and no record of what he says. Cases are reported where incredibly skilful thieves have secured considerable sums by cleverly imitating over the telephone the voice of wealthy business men, in other cases orders to buy or sell goods or securities have been repudiated by those who gave them by telephone, while the simple blunders caused by faulty telephonic transmission would fill volumes.

Elisha Gray, the well known Illinois inventor, recently patented a device to insure accuracy and accountability over the electric wire. The sender of a message can write it out at his desk, and an exact reproduction of the writing will be made at the other end of the circuit. There have been previous inventions which depended upon a variation in the intensity of the current or upon revolving cylinders with proved unsatisfactory. [illegible] Gray's device consists of two carrying

Telegraphic Wonders of the Future.

"I'll tell you what we'll have in this country in five or ten years," said a Chicago patent lawyer who keeps a keen eye on all things pertaining to telegraphy, "and that is a government postal telegraph with many thousands of miles of wire and using a printing telegraph or some such invention as that of Professor Elisha Gray, described in THE HERALD of Wednesday. Professor Gray, I understand, has great faith in his telantograph, and if it proves a success, commercially and intrinsically, it will revolutionize telegraphy. With that system, and with plenty of wire capacity, messages can be sent without the interposition of an operator. The writer of the message will be his own operator, merely sending his letter by wire instead of by mail, and his missive appearing at the other end in his own handwriting. I can easily see how, with some such system as this, the cost of messages can be brought down to 5 cents, and perhaps to 4 or 3 cents. This is not at all improbable, and I expect to see the day when the government then will transmit a short business message by wire from Chicago to New York, delivering them by carrier as it now delivers letters, for 3 cents, and longer messages for from 5 to 10 cents. In practical operation it will probably not be found desirable to send all messages by telautograph, and operators will be used. Here the printing telegraph will come in. In a few years you'll see girls sending messages by typewriter, the copy appearing at the other end neatly printed. In fact, that can be done now. Professor Gray has invented such a machine, and a young inventor from the country, backed by a syndicate of Chicagoans, of whom Superintendent Tubbs, of the Western Union, is one, is perfecting a marvelous printing telegraph, working night and day in his shop on Fifth avenue. I'll tell you one thing. Western Union people expect postal telegraphy. They know it is coming and are getting ready for it. If the government doesn't buy them out, watered stock and all, they will fight, putting rates right down to government notch. The danger is that before the government gets ready to do anything, Western Union will have bought up all these patents and thus got possession of the field for many years."

N. Y. Times

TELEGRAPH WITHOUT BATTERIES.

PANAMA, Nov. 10.—Señor Piedrahita, an electrician of Bogota, has patented a telegraphic instrument which, he claims, will revolutionize telegraphy, as it works without batteries. The Government appointed a committee of experts to examine into the merits of the machine. In their first report they say: "On the 12th of October we proceeded outside the city and placed the new apparatus in connection with the telegraph to the city, and without a battery we held communication with the main office. On Oct. 16 we practised another test, and sent messages over a wire 800 meters long, which was hung on posts without insulators, and some portions of which were allowed to trail along the ground. Once our machine was in order, we sent messages over this wire in Spanish, French, and English, and they were received without difficulty. The strength of the current received from us was tested, and it showed a density of 400 ohms, equal to a distance of 7½ leagues, and over this range we could have communicated had our wire stretched that distance."

State Republican, Lansing, Mich.
Jany. 16, 1889.

THE REAL INVENTOR.

Are We Indebted to Professor Morse for the Electric Telegraph?

A full and complete account of the invention of the telegraph appeared in The Century Magazine for April, 1888, and recently, in examining an old file of The New York Sun for the year 1857, I found the following editorial in the issue of Sept. 25, of that year, written by Moses S. Beach, the then proprietor and editor, and who knew from personal knowledge whereof he wrote. The article was entitled "Honor to Whom Honor Is Due:"

"The laying of the Atlantic cable has waked up hundreds of claimants for honors bestowed upon Professor Morse, and while each is so loudly telling his story, and is so impatient that it is coldly received, we will mention a few incidents connected with Professor Morse's own experience which we have never seen in print, and which lose none of their interest from the unassuming modesty of the other parties referred to.

"Soon after Mr. Morse's invention of the telegraph which has made him famous he was a professor in the University of New York City. As yet the invention was merely an idea, without material form. Among the students there was a son of Judge Stephen Vail, of Morristown, N. J., Alfred Vail, and the worthy professor had no auditor more interested in his supposed to be vagaries. Alfred was a young man of an active turn of mind, and he readily espoused Professor Morse's ideas. But the professor had no means; his brother Sydney looked upon him as a chimerical dreamer who deserved no help, and so Alfred Vail set about overcoming that difficulty. He told the story—visions and all—many times over to his father. The Judge was, as he is now, a liberal and generous man, with no small degree of contrivance about him. He became interested and invited the professor to his house. The result was a personal friendship and a year's experimenting at Judge Vail's expense.

"Alfred Vail entered into these experiments with his whole soul, and to him is Professor Morse indebted quite as much as to his own wit for his ultimate triumph. It was Alfred Vail who invented the far famed alphabet, and he, too, was the inventor of the instrument that bears Morse's name. But whatever he did or contrived went cheerfully to the great end. Alfred felt rewarded in seeing the gradual accomplishment of the dream.

"Judge Vail had a small factory near his house and separated from the Speedwell Iron Works, belonging to him, with water power, and in it the experiments were carried on. Three miles of copper wire, about four times as large as that used in the Atlantic cable, were purchased at Belleville, N. J. The wire was sent to New York and wound with cotton, under the supposition that it could not otherwise be made serviceable. Then the first clumsy registering machine was devised, and with it the writing machine, with its mechanical action by means of types. Their construction and abandonment for something better took place in the same factory, and there in an upper room, the remains of them—cog wheels, ratchets and slides—may, or a few days since might, still be seen.

"The first telegraph message ever sent under the so called Morse system was both sent and received in that same 'upper room,' and was dictated by Judge Vail—'A patient waiter is no loser.'

"Thence came the apparatuses subsequently exhibited in New York and elsewhere with such electrical effect. We have in our possession now a piece of that original three miles of wire, and we prize it as a memento—much more than our 'foot' of the Atlantic cable.

"The original plan for laying the lines of telegraph was by cables submerged in the ground. For this purpose the wire was to be inclosed in lead pipe and preparations were made for the introduction of the wire in the pipe simultaneously with its manufacture. Experiments showed, however, that with submersion the necessary insulation of the wire would be difficult, if not impossible, and the cheaper and more effectual method of suspension was adopted.

"Another incident and we are done. Morse was in those days, if he is not now, no mean hand at painting. To testify his appreciation of the kindness and invaluable 'material aid' rendered by the judge and his son Alfred, he painted a series of family portraits, and these specimens of his skill still adorn the walls of Judge Vail's parlors, and though not the perfection of art they display more than ordinary skill in the use of the brush.

"Judge Vail and his worthy son still live. The judge is as hale and hearty at 80 as most men at 50, and enjoys a well earned affluence in the old style—quiet retirement.

"Alfred Vail retains in maturer age the characteristics of his earlier years, and is now turning his attention to authorship."

With the statement that concludes your correspondent's article, that "a nephew of Mr. Morse is one of the best known duck hunters about town," I know of no reason for disagreeing, and will only express the hope that his claim to that distinction is more solidly based than was that of his uncle to being "the inventor of the telegraph." As a son of Alfred Vail I am naturally desirous that justice should be accorded his memory.—Stephen Vail in New York World.

Times-Star, Cincinnati, Ohio
Feby. 18, 1888.

Edison's latest is a harmonic telegraph, by means of which any number of messages may be sent over the same wire simultaneously, in either direction. He has been eleven years perfecting it. The Western Union people have purchased his exclusive use.

HAND AFAR, WRITING HERE

Professor Gray's Wonderful Invention, the Telautograph.

Messages Can Be Wired Any Distance in the Handwriting of the Sender—The Instrument's Utility.

In the invention of the telautograph Professor Gray has produced an instrument, or combination of instruments, the most wonderful by far yet devised for the control of that subtle yet illusive force known as electricity, and it is safe to say has paved the way for revolutionizing the existing system of telegraphy.

With the aid of these instruments every man becomes his own telegrapher, and the recipient of the message can fold his arms with the serene confidence that whatever is written by his correspondent will be instantaneously reproduced before his eyes, no matter how far away his correspondent may be, without his taking any part in the operation except to answer the message when it is received, or ask questions, as the message may suggest.

The telautograph is destined at no distant day to revolutionize the existing system of telegraphy. For newspaper publishers the telautograph is of still greater utility. The out-of-town correspondent can transmit his telegrams to his paper in his own handwriting in the very act of writing them, thus saving the loss of time involved in writing it out for the telegrapher in the transmitting office and of the rewriting by the telegraphic operator in the receiving office.

Even this, however, is not all. A correspondent of the Associated Press, for example, may report a debate in Congress at Washington and have that report reproduced simultaneously with his writing in

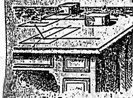
Professor Elisha Gray.

the newspaper offices of a dozen different cities.

Nor is the work of the telautograph confined necessarily to the transmission of written messages. The artist on the scene of railroad disaster or on the grand stand or the review of a procession may utilize it to send finished pictures of the scenes before him direct to the office of his newspaper. The idea of the telautograph first pro-

sented itself to Professor Gray about seven years ago, and he then went to work to produce a set of instruments capable of carrying out this purpose. After a long series of experiments he became satisfied that his control of the electrical current was not equal to the end he had in view, and he thereupon abandoned all attempts to perfect the instrumentality and devoted himself entirely to devising means for a better control of the current. Having obtained complete control of the current, Professor Gray again addressed himself to the task of perfecting the instruments which he has called the teleautograph.

This combination of instruments consists of a transmitter and receiver. These are shown in the accompanying drawing, the transmitter being designed by the letter A, and the receiver by the letter B. The



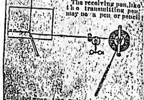
The Teleautograph.

mechanism of each is also shown by drawings, and the reader who has any acquaintance with electricity will have no difficulty in getting therefrom a general idea of their operation.

The Transmitter.

The transmitter is simply a pen or pencil such as is ordinarily used in writing, attached at its points to two silken cords placed at right angles to each other. The act of writing reduced to its simplest form is a repetition of vertical and horizontal movements of the pen, and the cords referred to are so arranged in combination with electrical instruments as to impart through magnets attached to the receiving instrument, corresponding movements of the receiving pen.

The receiving pen, like the transmitting pen, may be a pen or pencil



held between two rods placed at right angles to each other as shown in the drawing. These rods are controlled by magnets already spoken of and impart to the pen an upward or downward or horizontal movement corresponding with like movements of the transmitting pen. It follows from this arrangement that every movement of the transmitting pen is simultaneously and accurately reproduced by the receiving pen, and that the writer of the message may have his handwriting reproduced by the receiving instrument at his will. The receiving pen can be so adjusted as to enlarge or diminish the fac simile of the transmitting pen. The instruments are so constructed that the operator may write either on a pad in successive lines, as in ordinary writing, or on a continuous ribbon. In either case the paper rests upon a surface that moves downward as the pen is pressed upon the paper and upward as the pressure is relaxed. This upward and downward movement of the writing surface is utilized by means of appropriate mechanism to raise or lower the receiving pen, so that when the sender of a message lifts the transmitting pen entirely from the paper, he at the same time lifts the receiving pen, and as by the mechanism connected with the cords already referred to he controls the lineal movements of the receiving pen, it follows that the movement of the transmitting pen from right to left or crosswise is accompanied by the corresponding movement of the receiving pen.

It is evident, therefore, that he can turn back to any place upon the sheet or ribbon and make either erasures, interlineations or corrections at will. The receiver is also provided with means, which is under control of the operator of the transmitter, for shifting the paper after the completion of each line of writing, so as to bring it in proper position to receive the next line, and so on. The mechanism for shifting the paper is operated by pressing a button on the table beside the transmitting pen.

It is clear from what has already been said that both the transmitting and receiving pens, as well as the paper written upon by each, are under the perfect control of the person sending the message, and that it requires no special education or training to operate the teleautograph. On the contrary, any one who can write can send a message. The operation of the instrument is thus described by Professor Gray:

"The operator will take the transmitting pen in his hand and form the characters in proper sequence in the usual manner, moving the pen up and down and from left to right in forming the characters and writing the line the same as on ordinary writing. As the pen makes the down strokes in forming the characters the vertical cord will be unwound from the shaft of the interrupter attached, thereby revolving the shaft and moving a brush over a disc interrupting the current over the circuit repeatedly in quick succession, the number and rapidity of the interruptions being determined by the speed and extent of the movement of the pen.

"As the pen makes the upstrokes a spring attached to the shaft will rewind the cord and move the brush in the reverse direction, interrupting the current in the same manner."

The Receiving Instrument.

The following is the operation of the receiving instrument: Located adjacent to each of the rods which hold the receiving pen are a pair of reversely arranged receiving electro-magnets. [illegible]

"When the magnet connected with the vertical rod is energized by the closing of

the circuit in which it is located, the two parts of its armature will be attracted toward each other and toward the cores of the magnet. The connecting springs are so adjusted that one set are slightly weaker than the other, so that upon the magnet becoming energized and thus magnetizing the two parts of the armature, they will move toward each other and grip the rod in advance of being moved toward the magnet. After gripping the rod the two parts of the armature will move toward the magnet, thereby imparting a corresponding movement to the rod. As soon as the magnet is de-energized by the interruption of the current the weaker of the two sets of springs will draw the two parts of the armature apart, thereby releasing the rod, and the other springs will draw the parts back again against the back stop, [illegible] as often as the circuit [illegible] rupted, so as to energize and de-energize the magnet, and thus the rod and the pen will be moved with a step-by-step movement, the number and rapidity of the steps being determined by the number and rapidity of the interruptions in the current over the circuit. The movement thus given to the pen will constitute its upward movement in forming the characters. Whenever the second of this pair of magnets is energized or de-energized the same operation will take place, except that the rod and the pen will be moved in the reverse direction."

It is quite practicable to transmit drawings as well as written messages by the teleautograph, and Professor Gray says that the transmission can be made over five hundred miles as readily as over five hundred feet.

We present herewith a specimen of a written message from the receiving pen, which

J. W. Cushing Esq

Dear Sir

This is a sample of the experimental writing done by Elisha Grays Telautograph

Yours Truly

L. W. McPherson

Specimen of Telautograph Writing from Receiving Pen.

will give the reader an excellent idea of the perfect character of the work done by this marvellous instrument.

Professor Gray is of Quaker origin. He was born at Barnesville, Belmont County, O., on August 2, 1835. In early life he was a carpenter's apprentice, and it was then said of him that he was somewhat of a social nuisance because of his proclivity to acids and laboratory stuffs. At the age of twenty-one he entered Oberlin College, where he studied diligently for five years.

After finishing his collegiate education his health became very poor, so that it was not until he reached his thirtieth year that his attention was wholly devoted to electrical mechanism.

N. Y. Star, Dec. 11, 1888.

PRESIDENT GREEN EXPLAINS.

Inside Facts Concerning Some of Edison's Inventions.

The attention of President Norvin Green of the Western Union Telegraph Company was yesterday called to the following statements in an article on the early days of Thomas Edison, the inventor, published in a morning paper:

"The public doesn't know it, but there are in the safes of the Western Union patents which, if applied, would nearly double the efficiency of the telegraph to the interests of public convenience. They are not used because it costs money to put them into use, and there is no competition to compel the Western Union to do the best it knows how to do. The company buys Mr. Edison's inventions, partly because they may want to use them some day, but chiefly because they don't want them to get into the hands of people who might, in these, become dangerous competitors. They have to pay a fortune for each invention, and don't expect to use it when they get it, but the retention of their secure monopoly makes the policy a paying one."

"The Western Union," said President Green, "has not, to my knowledge, purchased an invention or patent of Mr. Edison during the past eight years. The company at one time had a contract with him, by the terms of which he was to receive, and did receive, a salary from the company, and, of course, had the refusal of all of his inventions during the time for which the contract was made.

"That contract expired eight years ago. It was made under the administration of my predecessor. I am not aware that we have suppressed any of the inventions of Mr. Edison. He is a versatile genius, and can make one thing in half a dozen different ways. He made an instrument to do the work of the quadruplex. The underlying principle was the same as that of the quadruplex, but it was constructed differently. To protect our property in the quadruplex we purchased this invention.

"Then Mr. Edison invented an improvement on the Bell telephone. We purchased that. Blake's transmitter was then introduced, and, as it was regarded as an infringement on Edison's patent, a lawsuit resulted. It was finally settled in this way: Bell's telephone was practically worthless without the Blake transmitter, and it was evident that the Blake transmitter was an infringement on Edison's patent. The Bell company could prevent us from using the Edison improvement, and we could prevent the Bell company from using Blake's transmitter. As the Bell telephone could not get along without the Blake improvement a compromise was effected, by which the Western Union receives a royalty of 20 per cent. for the use of the Edison improvement (the Blake transmitter).

"There may have been other inventions bought by the company under the terms of the contract, but nothing was bought for the purpose of suppression. The Western Union is constantly improving its service, and is always on the lookout for electrical appliances designed to improve the facilities of its business."

News, Lynchburg, Va. Nov. 11, 1888

Edison in an Emergency.

Soon Edison's mechanical skill became so noted in the office that he was made superintendent of the repair shop. It was not long before the value of his services was fully shown. The several telegraph companies then in existence—the Franklin, Bankers' and Brokers', Southern and Atlantic and Atlantic and Pacific—were using the Page sounder, the sole right to which was claimed by the Western Union company. Owing to the Western Union's success in a patent fight over the Page sounder, there came a time when an injunction was obtained, silencing all sounders of that type in the hands of rivals and practically putting a stop to our business.

Edison was called into the president's office and the situation explained. For a long time he stood chewing his tobacco, looking first at the sounder in his hand and then falling into a brown study. At length he picked up a sheet of tin used as a "back" for manifolding on thin sheets of paper, and began to twist and cut it into queer shapes, meanwhile we stood around looking on. Not a word was spoken. Finally Edison tore off the Page "sounder" on the instrument before him, and substituting his bit of tin, began working. It was not so good as the patented arrangement discarded, but it worked. In four hours a hundred such devices were in use over our lines, and what would have been a ruinous interruption to our business was avoided.—New York Star.

Herald, Baltimore, Md. Aug. 28 1888

BUSY INVENTIVE GENIUS.

The wonders of inventive genius have not yet been exhausted, nor are they likely to be for some time to come. In no branches of the arts and sciences are the inventors more prolific or more bent upon radical changes in existing methods than in telegraphy or phonography. The announcement that the Gray telautograph would soon be upon the market, providing a system that would enable the sender of a message to reproduce his own handwriting, at any distance by an electrical medium, caused much surprise, but no more than the announcement, some years since, that a quadruplex transmitter could be used upon a single telegraphic wire.

A New York expert, Mr. Craig, ex-manager of the Associated Press, has recently perfected an appliance which will enable 2,000 words per minute to be transmitted over a single wire and recorded in ordinary Morse system characters, which can be deciphered easily by an expert telegrapher at the rate of about 100 words a minute. By this new method, it is claimed that the cost of telegraphy can be reduced to two cents for 1,000 words, without materially interfering with methods now in vogue. By such a means, and including all the expense of labor, paper and other essentials, the total cost of sending 1,000 words from New York to California would be twenty-five cents, a vast difference existing between such a rate and that at present paid.

An inventor has now, with the Edison instrument as a basis, fixed up a device that will not only absolutely reproduce spoken words, but reduce them to printable copy, thus doing away, if successful, with the system of shorthand as at present constituted. A public trial is to be shortly given this remarkable discovery. Truly, it seems as if the field of invention is absolutely limitless.

Journal, Kansas City, Mo. May 14, 1889

A New Telegraph Instrument.

The freight office of the Burlington, in this city, is supplied with one of the new phonoplex instruments recently patented, by means of which two or more messages may be transmitted over the same wire at the same time.

The instrument makes it possible for the operator in Kansas City to wire St. Joseph or any station between these cities at the same time that the wire is being used to send a message to Creston, Ia. Not only can two messages be sent over the same wire at the same time, but they may be sent from opposite directions, and by means of this instrument in connection with the ordinary Morse instruments, messages pass each other on the same line without interruption.

The phonoplex is operated by means of an induced current and can be successfully used upon lines 100 miles and less in length. It can also be used in connection with duplex and quadruplex wires, making a long stretch of wire to be used in connection with intermediate stations. The whole equipment for an office takes up but little more room than a Morse machine and costs about $1.50 per month additional.

The advantages of the system lie in the fact that an operator can break in on the wire and reach any intermediate station without affecting through business. The Burlington is the only road in the city using the system and the operator, E. Pringle, is much pleased with the work that can be accomplished by its use.

The phonoplex emits a peculiar, sharp sound that is very distinct and in sharp contrast to the sound of the Morse transmitter.

Free Press, London, Ont, April, 11, 1889

ADVANCE IN TELEGRAPHY.

A new and important advance has recently been made in the interest of telegraphy, by the invention of an instrument called the phonopore, by means of which electrical effects are produced under conditions which, previously to this discovery, had been thought to make them impossible. If a telephone be inserted in a wire situated near to a line of telegraph wires, every passing current will produce noises in the telephone, notwithstanding that the telephone wire is perfectly insulated from the telegraph wires. These noises are known as induction noises, and it was while investigating the phenomena of induction, with the view of devising means to obviate its effects in telephones that Mr. Langdon-Davies made the discovery which has led to the important result referred to. His investigations led him to the conclusion that induction was caused by some form of electrical force, which might be separated from currents and which would pass freely through insulations impassible by currents. He further concluded that if this were so, a new series of instruments might be constructed for the utilization of this force, and capable of being put in operation in company with current instruments on the same wire. His conclusions have been proved to be perfectly correct by what has since resulted from the development of the principle. Instruments have been made which represent a system of communication of the highest practical utility, and by means of which Mr. Langdon-Davies has added a distinct and independent chapter to the history of electrical development. The only form of electrical force which finds free passage through these instruments appears to be always capable of being associated with sound. The inventor has therefore denominated the force "phonoporic impulse," and the instrument

the "phonopore." Suppose a telegraph line to be in full working order from one town to another, and that, owing to increase of business, it becomes necessary to provide some additional means of communication. All that is now necessary is to attach to the line at each end a phonopore, without in any way altering the existing instruments, batteries, or line. The phonopore can be worked at the same time as the ordinary telegraph instruments, and one line is thus made to do the work of two. If the line is already duplexed by ordinary duplex telegraph instruments, the addition of the phonopore will quadruplex it. If the line is—as a few trunk lines are—quadruplexed, the phonopore instruments will "sextuplex" or "octuplex" it. Indeed, it would seem difficult at present to assign any limit to the multiplex carrying capacity of the new system. In some recent experiments, says the London *Times*, messages were transmitted first by the ordinary telegraph instruments alone, and secondly by a phonopore instrument alone. In the next place, the ordinary telegraph instrument and the phonopore were worked together in opposite directions, duplex; after which the ordinary instruments and the phonopore were worked together in the same direction duplex. The final experiment consisted in the ordinary telegraph and both the phonopore telegraphs being worked together simultaneously through the single line. The three messages were perfectly transmitted, although some of the operators had not previously used the phonopore instruments. These experiments proved not only the complete possibility of simultaneous working, but that the phonopore can be arranged to work ordinary telegraph instruments, and that when used in duplex or quadruplex work it requires no special regulating or balancing. They also proved that any wire already provided with an ordinary service can instantly be duplexed by merely attaching the phonopore instruments. On a second artificial line there were installed two harmonic phonopore sounder telegraphs, constituting a duplex service without any arrangements whatever to balance the lines, and working through a resistance equivalent to that of about 6,000 miles of telegraph wire. Messages were perfectly transmitted through this line in both directions at the same time. [illegible]

THE TELAUTOGRAPH.

AN INSTRUMENT WHICH TRANSMITS HAND-WRITING AND PICTURES BY WIRE.

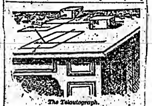
Prof. Gray's Greatest Discovery—An Invention Which is Expected to Revolutionize the Art of Telegraphy.

Written for The Republic.

In the invention of the telautograph Prof. Gray has produced an instrument or combination of instruments the most wonderful by far yet devised for the control of that subtle and illusive force known as electricity, and it is safe to say has paved the way for revolutionizing the existing system of telegraphy. With the aid of these instruments every man becomes his own telegrapher, and the recipient of the message can fold his arms with the serene confidence that whatever is written by his correspondent will be instantaneously reproduced before his eyes no matter how far away his correspondent may be, without his taking any part in the operation, except to answer the message when it is received or ask questions, as the message may suggest. The saving of time by this new system of telegraphy is so manifest that it needs only be referred to, and its advantages over the telephone and the existing method of telegraphing are, on the one hand, its applicability to long distance as well as short distance messages and the preservation of the message in the handwriting of the sender; on the other hand, its noiselessness and the confining of knowledge of the message to the sender and the recipient, and, over both, its absolute protection against leakage. From this brief general statement it is evident that there is no exaggeration of the truth in saying that the telautograph is destined at no distant day to revolutionize the existing system of telegraphy. [illegible] the telautograph is of still greater utility. The out-of-town correspondent can transmit his telegrams to his paper in his own handwriting in the very act of writing them, thus saving the loss of time involved in writing it out in the first instance for the telegrapher in the transmitting office, and, in the second instance, of the rewriting by the telegraphic operator in the receiving office. Even this, however, is not all. A correspondent of the Associated Press, for example, may report a debate in Congress of Washington and have that report reproduced simultaneously with his writing in the newspaper offices of a dozen different cities. Nor is the work of the telautograph confined necessarily to the transmission of written messages. The artist on the scene of a railroad disaster, or on the grand stand at the review of a procession, may utilize it to send finished pictures of the scenes before him direct to the office of his newspaper. This is certainly the crowning triumph of telegraphy to which electricians up to the present time have looked forward with feeling akin to the dreams of visionaries.

Prof. Elisha Gray.

The steps by which Prof. Gray has reached this achievement have been neither sudden nor accidental, but rather the steps of the explorer who climbs a toilsome ascent. The idea of the telautograph first presented itself to Prof. Gray about seven years ago, and he then went to work to produce a set of instruments capable of carrying out his purpose. After a long series of experiments he became satisfied that his control of the electrical current was not equal to the end he had in view, and he thereupon abandoned all attempts to perfect the instrumentality and devoted himself entirely to devising means for a better control of the current. As he says himself in the application for his patents, "variations in the constancy of the batteries or other generators of the current and in the strength of the currents, due to defective insulation, rate and other causes, occurred, which caused aberrations in the movement of the receiving pen, making the recording of a message uncertain and defective. The transmitting and receiving pens have been capable of only sufficient or slightly more than sufficient movement to produce a single character, the successive characters to make up the words and sentences being produced one after another in the same or substantially the same field." The difficulty in the way was that the professor found at his disposal a vibratory or variable current, uncertain and uncontrollable in its action. This is the current on which all previous attempts to produce a writing machine have been based. By years of study and innumerable experiments, Prof. Gray finally succeeded in producing what he calls a pulsatory current; that is to say, not an intermittent but a steady current, strengthened or weakened or removed, according to the requirements of the instrument. Prof. Gray says on this subject: "It is to be understood that when the currents are referred to as being broken or interrupted, they are not necessarily completely broken so as to entirely stop, but only that the currents are sufficient to interrupt it to release the armatures of the receiving magnets."



The Telautograph.

It is not necessary in this connection to go into a description, which would be too technical for the ordinary reader, of the means by which Prof. Gray has acquired this superior control of the electrical current. It is sufficient to say that he has accomplished the result by combination of instruments which the student of electricity can see for himself by reference to the reports of the Patent Office. Having obtained [illegible] control of the current, Prof. Gray again addressed himself to the task of perfecting the instruments which he has called the telautograph.

This combination of instruments consists of a transmitter and receiver. These are shown in the accompanying drawing, the transmitter being designated by the letter A, and the receiver by the letter B; the mechanism of each is also shown by drawings, and the reader who has any acquaintance with electricity will have no difficulty in getting therefrom a general idea of their operation.

The transmitter is simply a pen or pencil such as is ordinarily used in writing, attached at its points to two silken cords placed at right angles to each other. The act of writing reduced to its simplest form is a repetition of vertical and horizontal movements of the pen, and the cords referred to are so arranged in combination with electrical instruments so as to impart through magnets attached to the receiving instrument corresponding movements of the receiving pen. The receiving pen, like the transmitting pen, may be a pen or pencil held between two rods placed at right angles to each other as shown in the drawing. These rods are controlled by magnets already spoken of, and impart to the pen an upward or downward or horizontal movement corresponding with like movements of the transmitting pen, and it follows from this arrangement that every movement of the transmitting pen is simultaneously and accurately reproduced by the receiving pen, and that the writer of the message may have his handwriting reproduced by the receiving instrument in either small or large characters at his will. The receiving pen can be so adjusted as to enlarge or diminish the fac simile of the transmitting pen.

Prof. Gray's own description of the operation of the telautographic is as follows: "The transmitting pen is connected to operate circuit making and breaking devices, termed interrupters, located in two electric circuits and arranged to interrupt the currents passing over the respective circuits at short intervals, producing pulsations therein as the pen is moved in two directions crosswise of each other in forming characters, the number of pulsations in the respective circuits being determined by the distance which the pen is moved in the respective directions. These two circuits pass through the receiver and include electro motors termed receiving magnets, the armatures of which act through suitable connections to impart a step by step movement to the receiving pen in two directions, crosswise of each other, the number of steps in each direction being determined by the number of times the respective circuits are interrupted. By this means the movements of the transmitting pen in the two directions operate through the interruptions and currents passing over the circuit to impart corresponding movements to the receiving pen and thus reproduce the matter written or traced by the operator."

But while these devices provide for the synchronous movements of the transmitting and receiving pens, they do not provide for the wider control of the pens which enables the writer of a message to dot his I's and cross his T's and turn back and erase and correct what he has already written. The instruments are so constructed that the operator may write either on a pad in successive lines as in ordinary writing or on a continuous ribbon. In either case the paper rests upon a surface that moves downward as the pen is pressed upon the paper and upward as the pressure is relaxed. This upward and downward movement of the writing surface is utilized by means of appropriate mechanism to raise or lower the receiving pen, so that when the sender of a message lifts the transmitting pen entirely from the paper he at the same time lifts the receiving pen, and as by the mechanism connected with the cords already referred to he controls the lineal movements of the receiving pen, it follows that the movement of the transmitting pen from right to left or crosswise is accompanied by the corresponding movement of the receiving pen.

It is evident, therefore, that he can turn back to any place upon the sheet or ribbon and make either erasures, interlineations or corrections at his will. The receiver is also provided with means, which is under control of the operator at the transmitter, for shifting the paper after the completion of each line of writing so as to bring it in proper position to receive the next line and so on. The mechanism for shifting the paper is operated by pressing a button on the table beside the transmitting pen.

It is clear from what has already been said that both the transmitting and receiving pens, as well as the paper written upon by each, are under the perfect control of the person sending the message, and that it requires no special education or training to operate the telautograph. On the contrary, anyone who can write can send a message. The operation of the instrument is thus described by Prof. Gray: "The operator will take the transmitting pen in his hand and form the characters in proper sequence in the usual manner, moving the pen up and down and from left to right in forming the characters and writing the line the same as in ordinary writing. As the pen makes the downstrokes in forming the characters the vertical cord will be unwound from the shaft of the interrupter attached, thereby revolving the shaft and moving a brush over a disk, interrupting the current over the circuit repeatedly and in quick succession, the number and

J. W. Cushing Esq

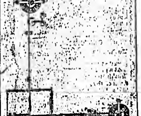
Specimen of Telautograph.

rapidity of the interruptions being determined by the speed and extent of the movement of the pen. As the pen makes the upstrokes a spring attached to the shaft will re-wind the cord and move the brush in the reverse direction, interrupting the current in the same manner. So long as the up or down movement of the pen continues the vertical cord acting upon a pulley will hold an arm against one of the stops and the local circuit will remain closed or broken, as the case may be, so that the pole changer will not be operated and the polarity of the current passing over the circuit will not be changed. As soon, however, as the movement of the pen is reversed, i. e., changed from up to down, or down to up, the movement of the pulley will be reversed and the arm will be rocked against its other stop, thereby changing the condition of the local circuit and operating the pole changer so as to change the polarity of the current passing over the circuit, and this change in the polarity of the current will take place as often as the up and down movement of the pen is reversed. As the pen is moved from right to left and left to right the horizontal cord and the spring attached will operate the brush of the interrupter connected therewith to interrupt the current over that circuit in the same manner, and this cord acting on its pulley will act to close or break the other local circuit and thus operate another pole-changer to change the polarity of the current passing over the circuit whenever the movement of the pen is reversed, the same as described in connection with the pole changer attached to the vertical cord." The following is the operation of the receiving instrument: Located adjacent to each of the rods which hold the receiving pen are a pair of reversely-arranged receiving electro-magnets. When the magnet connected with the vertical rod is energized by the closing of the circuit in which it is located, the two parts of its armature will be attracted towards each other and toward the cores of the magnet. The connecting springs are so slightly adjusted that one set are weaker than the other, so that upon the magnet becoming energized, and thus magnetizing the two parts of the armature, they will move towards each other and grip the rod in advance of being moved toward the magnet. After gripping the rod the two parts of the armature will move toward the magnet, thereby imparting a corresponding movement to the rod. As soon as the magnet is de-energized by the interrupting of the current over the circuit the weaker of the two sets of springs will draw the two parts of the armature apart, thereby releasing the rod, and the other spring will draw the parts back again against the back stop. This operation will be repeated as often as the current over the circuit is interrupted so as to energize and de-energize the magnet, and thus the rod, and the pen will be moved with a step-by-step movement, the number and rapidity of the steps being determined by the number and rapidity of the interruptions in the current over the circuit. The movement thus given to the pen will constitute its upward movement in forming the characters. Whenever the second of this pair of magnets is energized and de-energized, the same operation will take place, except that the rod and the pen will be moved in the reverse direction. From this it will readily be seen that in order to cause the up and down movements of the receiving pen to conform with the corresponding movement of the transmitting pen, it is only necessary to cause the interruption in the connecting circuit occasioned by the movement of the brush as the transmitting pen is moved upward to de-energize and energize the first magnet, and the interruptions in the same circuit occasioned by the reverse movement of the brush as the transmitting pen is moved in the reverse direction, [illegible] second magnet. To effect this the circuit, which, as before stated, includes both of those magnets, also includes another magnet of the polarized relay, the polarized armature of which is connected by a wire with the circuit between the two magnets first spoken of. A similar pair of reversely arranged receiving electro-magnets are located adjacent to the horizontal rod and included in another circuit and provided with armatures arranged to act upon this rod in exactly the same manner as the armatures of the other pair of magnets act upon the vertical rod, so that the energizing and de-energizing of the first of this second pair of magnets operate through its armature to move the horizontal rod and the receiving pen from left to right, while the energizing and de-energizing of the second magnet operates in a similar manner to move the pen in a reverse direction. This circuit is also provided with a polarized relay similar to that of the other circuit, which is arranged and acts to short circuit one or the other of the second pair of magnets whenever the polarity of the current passing over the circuit is changed, the same as described in connection with the other circuit. This polarized relay is so arranged that so long as the transmitting pen is moved from left to right, the current passing over the circuit will pass through the first of this pair of magnets and act to move the receiving pen in the corresponding direction, and that when the movement of the transmitting pen is reversed and the polarity of the current changed the current will pass through the second magnet of the pair and act to reverse the movement of the receiving pen.

"It has now been explained how the movement of the transmitting pen along or at right angles to the line upon which the message is being written in either direction will cause the receiving pen to move in the same direction,

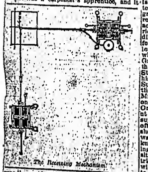


the movements of the latter pen being made up of a series of short steps. From this it follows that any movement of the transmitting pen in any direction oblique to the lines or intermediate between these two directions will cause the receiving pen to move in a corresponding direction, but with a compound movement made up of a number of steps taken at right angles to or crosswise of each other, the relative number of steps in each direction depending upon the obliquity of the direction in which the transmitting pen is moved. By this means the receiving pen is caused to follow any movement of the transmitting pen and thus reproduce a fac simile of whatever is written or traced by the latter."

It has already been stated that the range of the receiving pen can be made greater or less according to the requirements of the occasion, and from what has just been said it is plain that the receiving pen must correspond both as to range and pressure to the movements of the transmitting pen. From this it follows that it is quite practicable to transmit drawings as well as written messages by the telautograph, and Prof. Gray says that the transmission can be made over 500 miles as readily as over 500 feet. We have not been able to secure any specimens of drawings transmitted through the telautograph, but we present herewith a specimen of a written message from the receiving pen, which will give the reader an excellent idea of the perfect character of the work done by this marvelous instrument.

We give also an excellent portrait of Prof. Gray in connection with the subjoined biographical sketch. The professor's name is well known to the American public through the controversy over the invention of the telephone, and he is known to electricians the world over by his system of Harmonic Telegraphy. There is an erroneous popular impression that a recent decision of the Supreme Court of the United States settled the question of the invention of the telephone in favor of Prof. Bell. The fact of the matter is that the court did not pass on that question at all. It merely passed on the merits of a suit brought by the Bell Telephone Company against certain persons for infringement of patents, and Prof. Gray's name was lugged into the dispute without authority. The question of the invention of the telephone was brought up before the Commissioner of Patents not long ago on a motion to reopen the issue of the patents. The Bell people opposed the taking of testimony on this matter, but the Commissioner decided against them, and the testimony is now in his hands awaiting his decision.

Prof. Gray is of Quaker origin, and in his person bears the distinguishing evidences of his descent in a certain placidity and directness of manner born of his temperament and character. He was born at Barnesville, Belmont County, O., on August 2, 1835. In early life he was a carpenter's apprentice, and it



The Receiving Mechanism.

was then said of him that he was somewhat of a social nuisance because of his proclivity to acids and laboratory stuffs. At the age of 21 he entered Oberlin College, where he studied diligently for five years. His mental bent then was strongest in the study of natural philosophy, and to this he devoted all his spare hours. After finishing his collegiate education his health became very poor, so that it was not until he reached his 30th year that his attention was wholly devoted to electrical mechanism. This science fascinated him and monopolized his time, and he began to invent, his first attempt being to seek by internal mechanism a relief from the difficulties then embarrassing all telegraph lines arising from defective insulation. He constructed a self-adjusting relay, and it was a success. It was not largely used, however, as there was soon no necessity for the demand. In 1870 he invented (and two years later perfected the patent) the needle annunciator for hotels, which are now so largely used. The electrical annunciator for elevators was also invented by him about the same time. His next invention was an instrument for private telegraph lines, so constructed that any person who could read and spell was enabled to transmit messages upon it, by merely fingering keys similar to those on the type-writing machine of to-day. During the years 1873-75, Prof. Gray's attention was devoted to developing a system of "electro-harmonic telegraphy" for the transmission of sounds over the wires of a telegraph. He finally succeeded in sending, over a wire of 500 miles in length, nine different messages at the same moment, each message having a distinctive note, and each capable of being taken off at any number of intermediate points by simply tuning the receiver to the key-board on which each was transmitted. Theoretically, the number of messages that can be sent over a single wire may be increased to as many notes and semi-tones as the range of the gamut will permit. Prof. Gray was led to these investigations by a domestic incident, and among the earliest discoveries in connection with the experiments was the fact that not only simple but composite tones could be sent through the wire, and received, either on a metal plate or a magnet. By his method, different messages may be sent simultaneously, and a tune, with all its parts, may be sent hundreds of miles by wire, and be distinctly audible at the receiving end. This discovery underlies the whole system of telephones now in use, and is a splendid proof of Prof. Gray's right to priority of the invention. On February 14, 1876, Prof. Bell filed an application for a patent, and described his new invention in general terms as "new and useful improvements in telegraphy." In it he nowhere claims as an invention that it will transmit articulate vocal sounds or words. On the same day Elisha Gray filed a caveat, describing his invention as an "art of transmitting vocal sounds telegraphically." This was the earliest application of the kind in the world.

Mr. Gray thus specified his invention: "It is the object of my invention to transmit the tones of the human voice through a telegraphic circuit and reproduce them at the receiving end of the line, so that actual conversation can be carried on by persons at long distances apart. Mr. Bell secured this information, and the Department of Patents afterward improperly issued him a patent, to which he was in no manner entitled. Mr. Gray brought the matter to the attention of the Interior Department, and the United States brought suit against Mr. Bell to vacate his telephone patent. The case is still in the Superior courts, but there is no question but that right and justice will eventually place Mr. Gray in full possession of the privileges and benefits of his invention. In 1869 Mr. Gray formed the firm of Gray & Barton, at Cleveland, O., dealing in electrical supplies. They removed to Chicago soon after, and continued their business until shortly after the great fire of 1871. The firm was then consolidated in the corporation known as the Western Electric Manufacturing Company. Mr. Gray held the official position of general superintendent and electrician with the company until 1874, when he withdrew in order to devote his whole time to the protection of his patents and the telephone. He has made several improvements on the telephone, and when the great controversy is settled, and Mr. Gray secures his just right, he will doubtless give to the public an instrument vastly superior to that now in general use. Mr. Gray is president of the Chicago Electric Underground Company, but pays almost undivided attention to the litigation now in the United States courts. Mr. Gray's characteristic as an inventor is in avoiding more mechanical devices to accomplish results. Intricacy, in his mind, is a failure. He seeks to make electricity do his work, and therefore endeavors in his devices to train and harness it for that purpose. In 1878 he received the grand prize at the Paris exposition, and was conferred the degree of Chevalier and the decoration of the Legion of Honor by the French government. At the Electrical Exhibition at Paris in 1881, he was again honored with the gold medal for his inventions. Prof. Gray was conferred the degree of A. M. at Oberlin College, Ph. D. at Ripon (Wis.) College, and is a professor of electrical science in those institutions at the present time. He was also conferred the degree of Sc. D., and from Blackman University the degree of L. L. D. He is a member of the American Philosophical Society, the Society of Electrical Engineers of England, and the Society of Telegraph Engineers of London. He belongs to the Calumet and Union League Clubs of this city. He is a frequent contributor to the press, and has prepared several pamphlets, essays, etc., and issued a small volume entitled "Electrical Researches." Prof. Gray was married on January 1, 1862, to Miss Delia M. Shepherd of Oberlin, O. They have four children—Minnie, Annie, Edward and David.

Improvements in Electric Gas-lighting.—The various appliances that are now so successfully employed in lighting gas-lamps in halls, theatres, and in the streets, usually aim only to furnish the spark or hot wire that will fire the gas. The supply of gas must be turned by hand or by some mechanical means, and thus a part of the work of gas-lighting must still be performed at a waste of time, labour, and gas. To obviate this, and to save the gas thrown away after it is turned on and before it is lighted, a new system of electric gas-lighting has been brought out that turns on the gas, and at the same time sets it on fire. The same apparatus will also shut off the gas and extinguish the light, and by attaching it to a clock it can be made to light and put out the lamps automatically at any hour at which the clock may be set. The apparatus consists of a small electro-magnet, designed to be placed on the gas-jet just over the gas-cock, and a vibrating armature, and platinum wire for lighting the gas. The gas cock is a two-way valve, and having a small ratchet wheel in the place of the usual handle. This wheel is placed on one side of the gas pipe, and the electro-magnet is put on the opposite side; between them is hung a rocking-bar, supported on pivots on the pipe; at one end of this bar is the armature of the magnet, and at the other end is a pawl, playing in the ratchet wheel; a spring is also added to give the bar a vibrating motion when the magnet is excited by the current from the line. When the circuit is made by the battery at the station, the rocking-bar vibrates, and by means of the pawl turns the wheel part way round, and thus lets on the gas. The same current that sets the bar in motion also inflames the gas at the same instant. The gas being turned on, an eccentric on the side of the well breaks the circuit, and the wheel stops, leaving the gas turned on. After all the lamps in the circuit have been lighted in turn, the circuit is broken, and everything remains as it is till it is again closed. This second closing of the circuit produces the same effect on each apparatus in turn, but with the reverse effect in the lamp, for the wheel is pulled round by the vibrating bar, and the gas is shut off and the lamps extinguished. This same arrangement may be attached to single lamps in the house by omitting the electro-magnet, and substituting a small chain, that may hang below the lamp. On pulling this chain by the hand the pawl plays in the ratchet-wheel and turns on the gas, and at the same time lifts the platinum wire into contact with the jet, and the resulting spark fires the gas. To shut off the gas the chain is pulled again, and in the same manner the wheel is carried part way round, and the gas is shut off. This apparatus is designed for lighting street lamps by a cable laid just under the pavement, and from lamp to lamp. Circuits of 200 street lamps may be turned on and lighted, and turned off in a few seconds from a central office or the police station, either by hand or by means of clock-work. By a simple arrangement the same cable may also be exposed at each lamp-post, so that the police on beat may communicate by telephone with the station.—*Scribner's Monthly.*

THE TELEGRAPHIC JOURNAL.

Vol. V.—No. 105.

ELECTRIC CLOCKS.

The invention of electric clocks was a natural consequence of that of telegraphs. The idea seems to have been realised nearly simultaneously, like many other inventions which are based upon a new discovery, by several philosophers, Wheatstone, Bain, and Steinbeck among others, and a plentiful crop of most ingenious mechanical contrivances for effecting the desired ends was the result.

Electric clocks had for their principal object the multiplication of the indications of a single standard clock on numerous dials, which could be placed at any distance from, but in electrical communication with, the standard clock. This, we say, has been the principal object in view, but it has not been the only one. Very many ingenious devices were invented, and much mechanical skill shown, in producing clocks which would work without springs or weights, the motive power driving them being a galvanic battery. Very partial success was the result of the numerous efforts made, the principal cause of failure being the want of an efficient form of battery to produce the motive power. Even this seems to have been overcome, or was thought to have been so, as an electric clock company, which manufactured clocks driven by a battery, will still be recollected by most of our readers.

A little careful consideration of the utility of such forms of clocks can hardly fail to give rise to the conclusion that such an arrangement can be nothing more than a philosophical toy, and probably it was regarded as such, for the trouble of keeping a battery in order can hardly compare favourably with the trouble of winding up a clock weekly, or even daily. The novelty and not the utility of the invention must have been, after all, the inducement which led the curious to invest in such a form of timepiece. If the driving power of a clock in the first instance had been a battery, and afterwards weights or springs had been brought forward, there can be but little doubt that the former would at once have been cast aside. Such forms of clocks are now things of the past, though attempts have been, and are made, to again introduce them.

The multiplication of the indication of a single clock on several dials has met with much more favour, and indeed may be considered as a successful invention. The great advantage which such a system possesses is that it is only necessary for the standard clock to be a good time-keeper.

Boll

Continued

The methods adopted for carrying out a system of the kind are threefold. By one method the standard clock synchronises the swings of the pendulums of the companion clocks, as they are called, with its own pendulum, the clocks still being driven by weights or springs. This was the plan invented by the late Mr. Alexander Bain, and it is one of the best systems which has been tried, though it has not come into extensive use. Another method, which is the most common, is that of moving the clockwork of the sympathetic clocks by a step by step motion, worked by an electro-magnet, through which intermittent currents pass, governed by the motion of the standard clock. Lastly, we have the system which has received an impetus lately through the energy of Messrs. Barraud and Lund, and which, although not new, has not long been put into a thoroughly practical form. In this latter system the position of the hands of the clock are corrected at every hour, and although it is not such a refined arrangement as that of Bain, it is, perhaps, the most practical form which has yet been introduced.

The synchronising of clocks by electricity, although it must hold its own in cases where the different dials are at long distances apart, yet is likely to have a dangerous rival in pneumatic clocks, which have proved so successful at the hands of M. Meyer, of Vienna, and also, we learn, previously at the hands of Mr. Wenzel, of San Francisco. Whichever system proves the best there can be no doubt that there is a very large field open for workers in this particular branch of horology. The wonder is that more has not been done, but, as in every other invention, there is usually a period of mushroom growth, and then a period of stagnation, to be followed in time by a steady, though slow, progressive advance. The idea of time being laid on like water or gas can hardly be regarded as otherwise than chimerical; but there is usually a grain of probability in prophecies of this kind, and it is quite possible to conceive that most large warehouses will in time take advantage of a system which will keep all their timepieces in order and accurate in their rate of going with but little expense.

Jour Tel Apl 15, 78

ELECTRIC CLOCKS.—A correspondent of the *Scientific American* proposes to employ the Bell telephone principle of induced currents to the control of clocks by one standard time-piece. Under the pendulum of the standard is to be placed a magnet, wound with coils of wire, in circuit with a similar arrangement at each of the other clocks, so that when the iron bob of the standard pendulum swings past the coils at every stroke, a current will be induced in them, which will traverse the entire circuit, and operate on the pendulums of the dependent clocks, by means of their electro-magnetic coils and iron bobs.

Bean's Pneumatic Electric Gas Lighting Apparatus.—The novelty of Mr. Bean's invention consists in a combination of compressed and rarefied air to open and close the gas-cocks, and an electro-galvanic current, affording at the same instant a spark to light the gas flowing through the gas jet, so that a single operator can, without leaving his office, at will light or extinguish all the street-lights of a city or town.

Electrical News. July 15. 1875

Electric Signalling and Recording Apparatus.—William J. Philips, Philadelphia, Pa., April 28, 1875.—Arranged so that a watchman may send in a signal to central office, announcing his visit to any post, and at the same time register by suitable devices the time of the visit upon a dial in the box, all in an ordinary district alarm system. 1. The combination, with an electric signalling or alarm mechanism, of a recording mechanism, for registering at the transmitting station the time of transmittal of a signal therefrom, substantially as set forth.—2. The double-faced signal-box, provided with the signalling mechanism and the clockwork register, substantially as set forth.—3. The combination, with the circuit-breaking wheel and motor train thereof, of a pencil or other marking point of a registering mechanism and suitable connecting devices, substantially as set forth.—4. A double-faced signal-box, provided with the flanges R S and bolts U, substantially as and for the purposes set forth.—5. In the registering mechanism, the pencil-arm M, composed of the rigid parts *m m'*, united by a spring slip or piece, *n*, substantially as and for the purposes set forth.—6. The combination, with the arm M, provided with projection *e*, of the standard Q, provided with bevelled upper edge or end, substantially as and for the purposes set forth.

Electrical News Sept 9. 1875

Les Mondes. Vol. xxxvii., No. 15. August 12, 1875.

Contains a description of MM. Voisin and Dronier's Electro-Catalytic Lamp-lighter, which was invented and patented some months ago. Briefly described it is as follows:—A small glass vase contains an exciting liquid, and is placed inside a small wooden box, to the lid of which are attached two carbon plates and a zinc plate. The zinc plate is fastened to a rod projecting through the lid, and is kept above the liquid by a spiral spring, and the poles of the battery are led out from the box over above a small spirit-lamp of highly volatile spirit, such as paraffin; the two poles being connected by an excessively fine piece of platinum wire. When the rod is pressed down, the zinc plate at its end is immersed into the liquid, and the current engendered renders the platinum wire incandescent. The inflammable gas which surrounds the wick of the lamp, being immediately under the red-hot wire, becomes ignited, and the lamp so lighted is ready for use.

Fire-Telegraphs.

That a properly organised system of Fire-Telegraphy forms a most important adjunct to the operations of a fire brigade, can, we think, hardly be doubted by any who has given the subject a moment's consideration.

It has, on careful examination of practical and scientific facts, been deemed correct to state, that the difficulty in extinguishing a fire under ordinary circumstances varies at least with the square of the time that elapses between the outbreak of a fire and the arrival of the brigade at the spot. Further, there can be no question, that if the necessary steps were taken to quell a fire immediately it broke out, it would be well-nigh a matter of impossibility for the fire to assume serious proportions.

Bearing these two facts in mind, it requires but little perception to recognize the paramount importance of a speedy transmission of an alarm, upon the outbreak of a fire, to the nearest fire-station, whence immediate orders can be issued for its suppression. It is for this purpose that electricity can be and has been applied, and, theoretically speaking, a perfectly efficient system of Fire-Telegraphy would in this direction leave nothing to be desired.

In England Fire-Telegraphs are still a thing of the future, though in America and on the continent they have long been, and still continue to be, employed with success. The city of Boston, in America, was the first to employ them in that country in 1851; and from that time their use has spread over the whole of that continent, until Fire-Telegraphs now keep guard over no less than seventy-nine cities, while in Germany no town of large population is unattended by them.

Let us examine how London stands with respect to cities protected by a system of Fire-Telegraphy in the matter of slight and serious fires. London is served by a brigade with a well-earned reputation for bravery and ability, and the water-supply is most efficient, the total number of hydrants erected being at present 4,211. Yet here are the statistics:—

Year.	Small Fires.	Serious Fires.	Percentage of Great Fires.	
1866	1,018	323	24·2	
1873	1,382	166	10·7	10·1
1874	1,419	154	9·8	
1875	1,366	153	10·	

The above table, although showing that, notwithstanding the increase in population, the fire-brigade has succeeded in lessening by more than one-half, the proportion of serious to small fires, yet betrays the fact that 10 per cent. of our fires are serious ones. This number is far too high. Take, for instance, the statistics of the town of Berlin, which is not so efficiently served either with engines or water as London, but in which a system of Automatic Fire-Telegraphy is in operation:

Year.	Small Fires.	Serious Fires.	Percentage of Serious Fires.	
1873	873	28	3·11	2·82
1874	906	26	2·79	
1875	983	25	2·57	

In these tables by the term "Serious Fire" is meant one for whose extinction more than two engines or reels were required. Hence we find that in Berlin, which is not specially picked out as a favourable specimen, and only one of the many instances indicated by the copious statistics met with in the paper, the proportion of serious fires is less than one-third of that for London.

Having, it is hoped, thus shown the necessity for a system of Fire-Telegraphy, we may turn our attention to another portion of our subject—namely, the most efficient system of Fire-Telegraphy.

In order to guide us in our examination of the different systems, we may glance at those actually in operation.

In Hamburg there are two central stations, one in the hands of the Fire Department, the other in the hands of the police. Both are in immediate connection with each other and with seven district lines which run radially through the town and suburbs. On these lines are placed automatic annunciators and speaking stations, and from any of these an alarm can be immediately sent to the central fire-station, whence the necessary orders are issued.

The Automatic Fire-Annunciator as in use on the Continent is a simple mechanical contrivance, whereby a certain signal can, by the pulling of a handle be transmitted to the central station. It consists of a box closed by a glass front. It is opened by a key entrusted to the police or other officials, but in practice the glass front has to be broken in order to allow the signal to be sent. Inside is fixed a smaller cast iron box perforated below by holes through which pass three cords, two of which sustain a weight. To a third is attached a handle, which, when pulled, allows the weight to descend a certain distance. In descending, the cords which sustain the weight move round a simple system of pulleys in the interior of the cast iron box, thereby causing a cam or toothed wheel to revolve on the outside of the case. The teeth of this wheel are so cut, that when the cam revolves, it makes contact at certain points on its periphery with a spring, in connection with the line. The duration of these contacts determine the signal registered on the self-starting Morse-inker at the central station, and each annunciator has a different cam, in order that the signals received may be identified with that given by a certain annunciator. The cam is made to revolve twelve times when the handle is pulled, and when at rest it permanently touches the above-mentioned spring, so that a current is continually flowing through the line, ceasing only when a signal is sent. Each annunciator contains in addition, a galvanoscope, a lightning protector, and a Morse key, whereby messages can be sent.

Fifty cells of the Meidenger type are in use on each line.

There are in Hamburgh fifty-three Automatic Annunciators and fifty speaking stations, and the total length of the lines is 339,400 feet, consisting of overhead and underground wire.

Except when messages are being sent none of the Morse instruments are in circuit, except at the central station. Bells, however, remain in their place. Immediately a signal is received at the central station, the official in charge sends by means of a magneto-electric inductor, a Fire-alarm signal to all the speaking stations on the circuit, or, if need be, by means of a special commutator to all the stations on the seven circuits simultaneously. The operator at each of the various stations hearing his alarm-bell ring, takes up his position at the table upon which his instrument is fixed, and presses his foot upon a lever beneath, thereby cutting the bells out of circuit, and inserting his instrument. He is then ready to receive such directions as the central station shall think proper to issue. As soon as he leaves the table the lever, disengaged, returns to its former position, thus re-establishing the bells in the circuit.

The entire system has been erected at a cost of only £8,028, and is maintained at a yearly expenditure of £80.

The Fire-Telegraphs in Amsterdam differ only in the system of circuits. The whole town is divided into three circles, upon which are fixed speaking stations,

Electrical News Aug 12 1875

A project has been set on foot to connect all the public clocks of Paris with the chief clock of the Observatory. A telegraphic wire will unite it to the Luxembourg clock; which will in turn, by means of a series of wires, communicate its time to the Exchange, Law Courts, Town Halls, Churches, and most of the public buildings. The Observatory regulating time-piece is placed in the catacombs, so as to be away from the trembling influence of the ground; the time-piece scarcely varies one-tenth of a second in a year.

Electrical News Sept 30 1875

165,918. *Signal-Boxes for Fire-Alarm Telegraphs.* Moses G. Crane, Newton, Mass. Filed July 9, 1875.—Boxes in normally closed circuit. On the breaking of the circuit the armature levers are withdrawn by a spring. On taking against the fingers, closes a short circuit outside of magnet and circuit-breaking wheel, thus preventing a signal being given by any except the box first operated. In such box the mechanism is released by raising a lever having a lug in recess of the wheel, a tooth taking against a lever and locking it, to prevent the formation of the short circuit in each box. 1. In a fire-alarm signal-box the lever G, with its lug V and hook *t*, the flange *p*, and its notches V', the lever *b*, insulated plate *c*, and magnet D, all combined and operating as and for the purpose specified. 2. The combination of the lever H, the lever G, and the wheel F, whereby the said wheel is liberated and allowed to revolve under the stress of the motor C, as and for the purpose specified.

Electrical News Sept 16 1875

165,090. *Burners for Electrical Gas Lighting.*—Saml. Gardiner, jun., Washington, D.C.—1. The insulated globe holder I, in combination with the wires J and K, the one connecting with one burner, A, through its electrode E, and the other with the next succeeding burner, by the electrode F, with the said holders in the circuit throughout the series of burners, substantially as described. 2. The negative electrode E, as a part of, and a prolongation of, the separate metallic nipple C, and in combination with the burner-tip D, substantially as and for the purposes herein set forth. 3. The combination with the burner and the metallic globe holder I, of the wires J K, connecting said globe holder with the negative electrode E and the insulated wire G' of the positive pole passing through and beneath the globe holder, whereby a single burner may be lighted through the medium of said globe holder, as herein set forth.

THE ELECTRIC BELL SYSTEM.—The *Manchester Evening News* says that the electric bell system has been carried out on a larger and more elaborate scale at the Manchester City Hall than in any building in which that apparatus has been adopted. Wire of more than ten miles in length has been extended throughout the hall, all the departments being embraced by the system, while, however, each department has its own independent system.

Electrical News Sept 30 1875

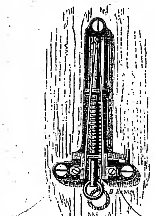
165,923. *Telegraphic Fire-Alarm Repeaters.* John N. Gamewell, Hackensack, N.J., M. G. Crane, Newton, and E. Rogers, Boston, Mass. Filed July 9, 1875.—1. The combination, with a break-circuit wheel of a telegraph repeater, upon which the lines of two or more circuits converge, of a governor, whereby, when a signal is being given over any one of the circuits, and repeated over the other circuits, the armatures of the magnets in such other circuits are locked in position, thereby preventing interference between the several circuits, as and for the purpose specified. 2. The auxiliary escapement movement, in combination with the governor J and the break-circuit wheel, whereby the reverse movement of the governor is not permitted to take place during several successive revolutions of the said wheel, as and for the purpose specified. 3. The auxiliary escapement movement, the circuit-wheel and its shaft, and the lever 25, combined and operating as described, whereby, after the winding up of the escapement by the revolution of the circuit-wheel shaft, the reverse motion of the said lever is prolonged and graduated, as specified. 4. The combination, in an electro-telegraphic repeater, of two electro-magnets in the same circuit, one of which has a larger core than the other, whereby there results an appreciable difference in the periods required for them to be charged and discharged, respectively, as and for the purpose specified. 5. The device described, whereby the breaking of any one of several circuits connected with the repeater for the purpose of signalling occasions the break-circuit wheel to be cut out from that circuit by closing the same over auxiliary fingers *x x'*, all combined and operating as and for the purpose specified. 6. The auxiliary magnets F F', with their armatures and hooked lever M, in combination with the armature lever H and swinging lever D, as and for the purpose specified. 7. The combination of the swinging lever D with its two stop pins, and the arm *l*, with its two fingers *s s'* upon the break-circuit wheel shaft, as and for the purpose specified. 8. The combination of the cam 28, levers 22 and 25, and sliding bar 18, as and for the purpose specified. 9. The combination of the governor J, bar 18, lever 25, and latch 37, as and for the purpose specified. 10. The lever I, with its short arm 10, the armature lever H, and lever D, and the governor J, combined and operating as and for the purpose specified. 11. The auxiliary escapement *y y'*, with its train 31 32, in an electro-telegraph repeater, employed to graduate the movement of the mechanism by which said train is actuated relatively to the movement of another telegraphic repeating mechanism.

(22) E. T. H. asks: 1. I want to make a magnet to place in a fire alarm telegraph circuit. The circuit is composed of about 8 miles of wire, with 15 stations. Of what size shall I make my magnet? A. Make the coils of copper wire, and let the resistance be 25 or 30 ohms for each magnet. 2. In a late number of your paper, Mr. Sawyer says that it requires 10 cups of Grove's cells to heat a fragment of platinum wire. In a former number, in an illustrated description of an hydro-electric lamp, the illustration shows only 1 small cup. What is the smallest amount of battery power required to heat platinum wire to a red heat? A. That depends upon several circumstances. A single cell of bichromate battery (without porous cup) will heat from a quarter to half of an inch of No. 40 platinum wire to a white heat.

13

La prévoyance humaine s'est depuis longtemps inquiétée de moyens qui, sans empêcher la déclaration de l'incendie, puissent du moins en donner le signal et permettre d'apporter de prompts secours. Les procédés mécaniques et chimiques que différents inventeurs supposaient propres à remplir ce but, furent aussi vite abandonnés que conçus et les efforts se portèrent sur cet agent merveilleux l'Électricité.

MM. de Gaulne et Mildé présentent un appareil avertisseur d'incendie électrique qui réunit les qualités les plus désirables : son organisme est simple, solide; il ne peut être altéré par un usage des plus prolongés. Basé sur le principe de la dilatation des métaux, il est donc d'une très-grande sensibilité, ses effets sont certains et instantanés.



Sur un fort bâti métallique triangulaire, deux lames sont fixées parallèlement par leur base, au moyen de plats qui les tiennent élevées de un centimètre du bâti. Celle de droite articulé à sa base, où se trouve une vis micrométrique avec un index qui parcourt un secteur portant les divisions thermométriques des divers degrés dans lesquelles peuvent s'effectuer les effets de l'appareil. Celle de gauche est fixée sur son plat et isolée du bâti par une rondelle en ébonite; ces lames sont composées de trois métaux qui ont entre eux les plus grands différents coefficients de dilatation : l'acier trempé, le cuivre rouge et le zinc. Cette composition trimétallique est nécessaire, elle permet d'obtenir des effets de dilatation et de contraction réguliers; ce qui serait impossible si les lames étaient composées d'acier

139,692. J. Vansant, San Francisco, California. *Electrical Gas Lighting Apparatus.* Dated February 3, 1873. The gas valve at the burner is operated directly by an electro-magnet, whose helix is also employed in exciting a secondary induction coil for igniting the gas by a spark. A permanent magnet is employed with the electro-magnet, so as to obtain both attraction and repulsion; and to preserve the permanent magnet from deterioration it is surrounded by a coil whose direction of current is never reversed. The apparatus, including the gas burner, is insulated from the gas-pipe by an interposed tubular section of non-conducting material. By the use of a peculiar circuit breaker and switch the battery power is successively transferred to several series or districts of street lamps.

raréfié se précipite rapidement dès qu'un commencement d'incendie se manifeste; les lames en communication directe avec cet air ambiant sont instantanément impressionnées : car ces couches supérieures peuvent promptement atteindre 10 à 15 degrés d'élévation de plus que celles inférieures.

Outre son caractère essentiel d'avertisseur d'incendie, l'appareil de MM. de Gaulne et Mildé se prête encore merveilleusement à trois applications importantes de l'électricité aux besoins de la vie :

1° Formant tirage, il sert d'appel dans les installations de sonneries électriques aux usages administratifs ou domestiques;

2° Placé dans les théâtres, musées, arsenaux, banques, usines, etc.; il remplit l'office de contrôleur de rondes;

3° S'agit-il de la surveillance d'un chauffage général, soit dans les établissements publics ou particuliers comme hôpitaux, prisons, bains, étuves, serres-chaudes, etc, l'appareil, avec une rigoureuse exactitude, prévient chaque fois que les degrés de *maxima* et de *minima* auront été dépassés.

Par ses services multiples et son extrême bon marché, la sonnerie électrique s'est aujourd'hui tant généralisée que l'application de ces appareils ne nécessite point d'installations spéciales et coûteuses, telles qu'ont entraîné tous les essais en vue de prévenir des premières atteintes de l'incendie. Leur prix minime (12 fr.) n'augmente que très-insensiblement la dépense d'un service de sonneries électriques; ils s'adaptent parfaitement aux services existants sans en rien modifier.

C'est particulièrement à ses diverses fonctions que cet appareil doit sa supériorité sur ceux mis à l'essai jusqu'à présent, car son usage journalier comme tirage d'appel ou de contrôle, permet à chaque instant de juger du bon état de l'installation; et, à chaque fonctionnement, un index métallique entraîné lors du tirage, s'interpose par frottement entre les surfaces de contacts des deux lames, les tient ainsi en bon état de propreté; condition essentielle au passage du courant. Tandis que si l'appareil devait se borner au seul rôle d'avertisseur d'incendie, après quelque temps de son installation, les surfaces de contacts se couvrant d'oxyde, de poussières ou d'autres corps isolants, par suite des condensations de vapeur qui s'opposeront au passage du courant, il ne pourra donc y avoir de signal, lors même que les lames se toucheraient, parce qu'à leur surface de contact il y aura solution d'agrégation moléculaire.

C'est, en effet, ce qui s'est toujours produit dans les essais antérieurs. L'insuccès fut encore plus grand avec les appareils à mercure; car, outre que le mercure est un des métaux les plus oxydables, mais encore le tube de verre dont il est enveloppé, étant très-mauvais conducteur de calorique, rend tout au moins les effets tardifs et les ravages de l'incendie seront déjà bien considérables lors même que le signal serait donné.

Les services multiples et la sûreté des effets de l'appareil

AVERTISSEUR ÉLECTRIQUE D'INCENDIE

Système de Gaulne et Ch. Mildé.

Chacun est journellement saisi au récit des désastres que laisse sur son passage l'incendie. Nos salles de spectacles s'écroulent, nos manufactures sont dévorées par ce fléau destructeur; et nos plus belles œuvres d'art deviennent sa proie, sans qu'un secours salutaire ne vienne apporter d'autre remède que de circonscrire le désastre.

FIRE ALARMS.

What more dreadful death can be imagined than that by burning? Witches and devotees were burned at the stake because cruel persecutors could contrive no more dreadful form of death. The shock which was given to humanity all over the country when, on the 13th of January, the tidings spread that a family had been burned to death in New York City, in one of the centers of civilization, in an elegant residence provided with all the modern improvements, and filled with every luxury that wealth could furnish, will not be quickly forgotten. It, too, has a lesson, both to builders and to the public. Four lives were sacrificed because the fire had gained too great a headway before it was discovered, and had cut off the means of escape. Against the insidious attacks of suffocating gases from leaking gas pipes or defective flues we cannot be warned by any sort of alarm, but fire is a force capable of making known its presence, and of awakening the inmates before it is too late. Several different forms of fire alarms have been suggested, such as torpedoes or muskets which should go off with a loud report when the heat reached a certain point. Fuses to ignite at any temperature above summer heat, and thus communicate with some explosive substance, or set in operation an electric bell, have been patented, but not very frequently used.

A very simple fire alarm, which is cheap and practical, has been suggested by Dr. Von der Weyde. A small weight of lead or iron is made to adhere to the ceiling of each room with a piece of wax. When the temperature becomes elevated above that of the ordinary atmosphere, the wax will lose its adhesiveness and allow the weight to drop. The weight can be attached by a wire to all the bells in the house, or to sound any alarm extemporized for the purpose. The weights should be kept away from stovepipes and out of the sun, and one should be placed in each room and hallway. They will not fail to give the alarm when there is an excessive increase of temperature, and no house should be without them. This alarm is not patented, and is free to be used by all without money and without price.

It might be objected by some that these strings with weights attached would not be ornamental. This would depend on the style of weight employed; for the parlor it could take the form of a little hanging basket with flowers; for the nursery it might resemble a jumping jack; in the library a thermometer or paper-weight; in the smoking room a cigar holder; for other rooms appropriate objects will suggest themselves.

Persons who have the wires of the American District Telegraph Company in their houses should combine them with one or other sort of automatic fire alarm. In offices and manufactories, if night watchmen are not employed, this would be especially useful, and would save millions of dollars' worth of property.

As prevention is better than cure, fire-proof paints, and timber saturated with salts which prevent its rapid combustion, suggest themselves, as also increased means of exit in case of the stairs taking fire, as happened in Mr. Jacob Steiner's house.

GAS PRESSURE ALARM.—When two neighboring buildings are illuminated by gas derived from the same source it frequently happens that the extinction of the lights in one building causes the pressure of gas in the other to become greatly increased, and sometimes to result in accident. M. Launay proposes, as an alarm to give warning of this over pressure, a bisulphate of mercury battery, in which the liquid is in communication with the gas by means of a siphon, so that the pressure of the gas, in varying, raises or lowers its level. If the pressure is above a certain fixed limit, the liquid is raised so as to come in contact with the metallic portion of the battery, establishing a current which sounds an electric alarm. M. Launay also suggests that a simple method of determining leaks in gas pipes throughout a building is to force some strongly odorous smoke into the supply pipe. The fumes of incense, for example, escaping in any room, would be readily distinguished from gas, and the locality of the leak discovered.

The Electrical Railway Alarm.

THE bell rope commonly used on our railways, while it is very serviceable for short trains, is not of much use on long freight trains, because the weight and friction of a long cord is such that the rear portion of the cord may be broken without moving the forward portion. Thus, if the coupling of the rear cars of a long freight train breaks and the train separates, no alarm will be sounded on the engine gong, because the rear portion of the cord breaks while the front portion, to which the bell is attached, is not moved. An improvement which overcomes this difficulty consists in placing a magnetic bell hammer upon the engine, together with a small electrical battery, and in providing each car with a set of wires, joined by flexible joints, so arranged that while the train remains united all is well, but should any of the car couplings or wires break, the gong on the engine will instantly commence ringing. The same device may be employed by the conductor to give any signals that he may desire to the engineer.

PRIZE OF £25,

to be awarded to the Author of the best paper on "The Evidence of the Theory of Correlation of Physical Forces as applied to Electricity and Magnetism," received by the Editor of this Journal on or before January 1st, 1874. Each paper submitted for competition must describe original experiments. Each paper to bear (on every leaf) some word or motto by which it may be recognised. The same word or motto to be inscribed on a sealed envelope containing real name and address of competitor. The papers not selected will be destroyed with the envelopes unopened. Papers to be addressed to the Editor, and indorsed "Sabine's Prize." The best papers will be selected and submitted to a Committee of well-known Electrical Authorities (whose names will be published), who will award the prize for the most carefully prepared paper, irrespective of the view taken by the Author, whether favourable or unfavourable to the new theory. The award to be final. The Prize Paper to be printed in the columns of this Journal.

BURGLAR ALARMS

in great variety are exhibited. The simplest is one which travelers can carry in their trunks or even pockets, and which will be found an excellent protection against the entry of thieves into an hotel room. It is a small wedge-shaped case of metal, containing a gong, the hammer of which is actuated by clockwork. The latter is wound, and the device is placed on the floor with the edge of the wedge just in front of the door. When the door is opened, however gently, from the outside, it strikes against the wedge, and suitable mechanism therein frees the spring of the clock train so that the gong is loudly and continuously sounded. The noise is sufficient to arouse the soundest sleeper. The invention might easily be adapted for windows as well as doors.

ELECTRIC ALARM AGAINST SUFFOCATION BY ILLUMINATING GAS.

Burglar alarms have come into extended use, in this country at least, and to them have been added fire alarms, to go off when a certain temperature is reached; and it has been suggested that a suitable alarm for coal gas from leaky stoves could be added, making use of the property that carbonic oxide possesses of precipitating palladium salts. Another modification has been invented by Ansol, for detecting the escape of street gas in a room. It possesses the advantage of simplicity, and its operation depends on a physical law, not a chemical one, namely, that the lighter a gas is the more rapidly it diffuses through a porous membrane.

The apparatus consists of a pear-shaped vessel covered with a porous membrane or unglazed earthen plate. This vessel has attached to it a U-shaped tube filled with mercury. One pole of the battery dips into the mercury, the other terminates just above the surface of the mercury in the open end of the tube. If this apparatus is placed in a room where coal gas is escaping, the gas enters through the porous plate more rapidly than the air can escape; a certain pressure is produced, which causes the mercury to rise in the open leg and complete the circuit, thus giving the alarm. It is said that a comparatively small amount of gas in a room will set the apparatus in motion. A similar apparatus with the opposite arrangement of the terminating wires could be employed for detecting a large escape of carbonic acid from any source, for this gas is so heavy as to at once produce a partial vacuum in the pear-shaped vessel, and, of course, a fall of mercury in the open leg. The amount of carbonic acid requisite to vitiate an atmosphere is, however, so small that it would probably be without effect on this instrument. There may be other cases where the pressure of gases much heavier or lighter than air could be detected more quickly by this than by the ordinary methods, as in coal mines and wells; while an advantage is that signals may be automatically conveyed to any desired distance. This seems, at least, a promising field for inventive genius and research.

3795. MAGNETO-ELECTRIC TELEGRAPH SIGNALLING, G. Zanni, Highbury.—Dated 1st November, 1875.

The first part of this invention relates to improvements in magneto-electric apparatus applicable for signalling between the captain of a vessel and the engine-room and steersman, and for railway and other signalling purposes. For this purpose a magnet is arranged in combination with a crank and axis actuated by hand or by the steam engine of the vessel or the locomotive of a train or by other suitable motive power in connection with keys for transmitting the proper signals from one situation to another as may be required. In place of employing a magnetic current as previously described, the apparatus may be actuated by a voltaic current by means of a suitable battery or batteries, the mechanism being slightly modified for this purpose. The apparatus previously described may be employed for telegraphing type printing purposes in accordance with another part of these improvements. The magneto apparatus in this arrangement is actuated by means of a small crank in connection with a key-board of suitable form, having as many keys as there are figures or characters to be transmitted. The same result as that previously described may be obtained in accordance with this invention by employing battery power in place of magneto-electric apparatus, suitable modifications being made in the apparatus for this purpose. Another part of these improvements relates to magneto-electric telegraphic apparatus known as the A B C instrument. In this apparatus a suitable transmitting key-board is employed, with a crank axis which gives motion to a disc or making and breaking contact, having as many conducting and non-conducting divisions as there are letters or characters in the receiving dial. The above described apparatus may also be actuated by battery power in place of magneto-electric apparatus by suitable modifications of the transmitting apparatus. The apparatus previously described may be arranged so as to carry a disc or other signal in place of a pointer, in order to exhibit signals upon a line of railway for working the block system of signalling, in combination with the arrangements of apparatus described in the specification of letters patent granted to the inventor, dated 2nd November, 1872, No. 3262.

doubt, to a very great extent, the irregularity in the results of serious fires, as shown in tables which I have compiled. From these we see that some towns with imperfect telegraphic arrangements give a lower percentage of serious fires than other towns in which an almost perfect system of fire-telegraphs exists. This is, however, only exceptionally the case, and we shall always find that efficiency of the brigade, abundance of water-supply, solidity in the construction of buildings, or a judicious choice of fire-proof materials, are the reasons for these apparently contradictory results.

For "absolute security" the highest perfection of these five conditions is required, and therefore these tables can only be considered as demonstrating the results of one of the conditions; they go to prove that where fire-telegraphs are in operation much better results are obtained than where they are not in operation.

There is yet to be considered the other difficulty in the way of a true comparison of the results in the percentages of serious fires, viz., the want of a standard unit to determine a "serious fire." My classification is, as far as possible, based upon the definition that a "serious" fire is such as requires more than two engines or fire-reels for its extinction.

From statistics we see that towns with perfect fire-telegraph systems have their serious fires reduced to an average percentage of 4; the less perfect systems show more frequently serious fires, reaching an average number of 17; while the percentage in towns possessing no fire telegraphs reaches as high as 29.

It could easily be shown that the percentage of fires resulting in "total destruction" must likewise be exceedingly high in towns without fire-telegraphs, but it suffices to give a single case which well represents the average of their class, viz., the town of Antwerp, in Belgium, with 160,513 inhabitants. The total number of fires during the two years of 1873 and 1874 was 37, with 5 "total destructions:" thus giving the alarmingly high result of 13·5 per cent. of fires ending in total destruction.

The city of Paris, on the other hand, furnishes ample proof of the reduction of fires resulting in total destruction after the introduction of fire-telegraphs. I regret that I have not been able to obtain a classification of the Paris fires according to the basis adopted in this paper, viz., proportion between "total number" and "serious fires;" but I have obtained from the chief office of police, statistics which are classified according to the value of damage done. This list shows that the average "total destruction" have diminished 50 per cent. since the year 1870, the time in which the fire-telegraph was introduced.

One of the strongest arguments in favour of a fire-telegraph system is the saving on insurance, which must naturally follow from a reduction in the percentage of serious fires. It would be departing from my subject too much if I were to lay before you an estimate of the millions that have been saved, or the millions that may be saved, by the adoption of fire-telegraphs. Such calculations I leave to the insurance companies, and will only endeavour to show by a few data the financial and economical value of the system. In the town of Brunswick in Germany, in one year, when there were no serious fires, only £282 was paid by the insurance companies. In two other years, when there were four serious fires, £17,000 extra was paid:—

Year.	Fires.	Serious.	Insurance Value.	Insurance Paid.
1873	95	2	£9,093,870	£7,939
1874	96	0	9,746,648	282
1875	101	2	10,198,338	15,364

I may add to this table the most recent communication which I have received on this subject. The Superintendent of the Salford, England, fire-brigade, Mr. Robert Hall, wrote me on the 17th October last year: "The complete system of telegraphs in this borough has enabled me to save many thousands of pounds in cases of fires."

In America the same result is obtained. The Superintendent of the St. Louis Fire Telegraphs, H. C. Sexton, in his report of 1860, says: "A comparison of the two years' working of the department prior to the establishment of the electric alarm, with the two subsequent ones, shows the following results: "From 1856 to 1858 the amount of losses was $1,803,315, against $710,301 from 1858 to 1860, showing a diminution of $1,097,911, or $548,955 annually, and, on the principle that prevention is better than cure, we claim for the fire-alarm telegraph a large share of the credit in saving that amount." The chief of the Montreal fire-department, A. Bertram, in his report of 1866, says: "As the simplest illustration of the great value of the fire-alarm telegraph we have the fires and loss for a fair average before and since its introduction:—Before, 85 fires, $140,088 loss; since, 99 fires, $35,428 loss." Mr. Joseph L. Perley, Chief Engineer of the fire department of New York City, and now President of the Board of Fire Commissioners says: "It would be difficult to estimate the value of the fire-alarm telegraph. I have known cases where lives have been saved by the quick method of communicating the intelligence of fire—the value in money would amount to millions." The Honourable J. C. Cuyler, one of the Fire Commissioners of Albany, testifies: "I give it as my opinion, from my knowledge of the localities in which fires have occurred, the character of the buildings, and the nature of their contents, that it would be a moderate estimate to say that it (the fire-alarm telegraph) has effected in Albany a saving of at least one quarter of a million dollars annually;" and the chairman of the Board of Fire Commissioners of Hartford says: "To the best of my judgment, our losses since the introduction of the fire-alarm telegraph have not been one-tenth of what they were before."

That the necessity for extended fire-telegraph systems is equally felt in Great Britain may fairly be judged from a report of 1875 from the chief of the Dublin Corporation Fire Brigade Department, Mr. Robert Ingram, who says:—"I furthermore would recommend that the different police stations throughout the city be connected by magnetic telegraphs with the chief fire-station, with coloured signals attached to alarm bells. By this means we should be enabled to get quicker intelligence of the locality of fire, as at present the police are obliged to take the first means of conveyance, such as a car or cab. It is my impression, from my knowledge of the city, that a vast amount of property might be saved by this means of communication with the brigade."

A secondary, though no less interesting, advantage to be gained by fire-telegraphs has been pointed out to me by Mr. Frobeen, chief of the Memel Brigade, who says:—"After forty years' experience as chief of the brigade, I can assure you that since the establishment of the fire-telegraphs there are not only very few serious fires but there are no cases of incendiarism, so little chance of success being left to the incendiary in a place where most of the fires are quenched in their infancy."

From a table of Stettin fires, from 1865 to 1875, it appears by far the greater number were extinguished in their infancy, and they furnish good testimony of the efficiency of the fire telegraphs, and go far to corroborate Mr. Frobeen's opinion. The truth of it must, however appear evident to all, upon the meanest consideration, for it stands to reason that the incendiary will be far less likely to carry out any of his nefarious schemes when the certainty exists that in the course of a few minutes a policeman, or other officer connected with the fire-brigade, will be on the spot, and so able to detect him. I need not, therefore, waste more of your time in discussing the point.

I am well aware that the statistics I have laid before you are far from complete, but any addition to them cannot materially alter the conclusions to which they all point. These conclusions briefly summed up are:—

(1) That the towns without fire-telegraphs are liable to a very high percentage of serious fires, the cause of this being unquestionably the time lost in calling out the fire-brigade.

(2) That the employment of fire-telegraphs in all cases leads to a decrease in the percentage of serious fires, and that the more perfect the fire-telegraph is the greater the reduction effected in the percentage of serious fires.

The principles of construction claimed by a perfect fire-telegraph system are shortly these:—

(a) Entire control and management of the line by the fire-brigade department.

(b) Underground cables.

(c) A system of circles or rails, with a suitable number of speaking stations and automatic fire-annunciators, all terminating in one or more central stations, from which commands are issued to the entire system.

(d) That the stations and annunciators be so chosen that each part of the town be as near as possible to a point of alarm; that the closed-circuit system be preferably adopted, and the Morse in preference to other speaking instruments.

These points might be modified as local circumstances require.

THE NEW NOMENCLATURE IN GERMANY.

THE following letter bearing on this question has just been published:—

"BERLIN, Germany, January 5th, 1877.

"*To the Secretary of the American Iron and Steel Association:*

"SIR,—Every system has its defects; hence, every nomenclature also. The settlement of a system can therefore only be founded upon a compromise, and a system so made is the better the more its nomenclature covers the principal abstracts, and leaves the uncertainties to the lowest divisions. That was my opinion as I put my name under the International Committee's report.

"Our ancestors made by the ways of the direct process, or of the charcoal finery, two kinds of forgeable iron, which always differed essentially in the amount of carbon, had, in consequence, essentially different physical properties, and were used for essentially different purposes. The intermediate kinds of iron were not in use, and were therefore not purposely produced. The puddling process originated at first an intermediate product, the so-called 'fine-grained iron.'

"All these products were obtained in a pasty state. Now comes the Bessemer process and produces a fluid, forgeable metal, and several adjoining processes do the same. Fluid irons are now easily made of different amounts of carbon, and every intermediate product is blown without difficulty. From this time the property of hardening no more stands in the foreground; it goes back, and the properties which are a consequence of the fluid state take the leading place. At the same time arises the necessity of a new nomenclature.

"The nomenclature of the International Committee is known. Let me show the system:—

Iron,
- Forgeable; difficult to melt: Forgeable iron, I.
  - Obtained in a fluid state: A. Ingot iron.
    - Hardening: 1. Ingot steel.
    - Not hardening: 2. Ingot iron.
  - Obtained in a non-fluid state: B. Weld iron.
    - Hardening: 3. Weld steel.
    - Not hardening: 4. Weld iron.
- Not forgeable; easy to melt: Pig-iron. II.
  - With amorphic carbon only: C. White pig.
  - With graphite: D. Gray pig.

There may be added, called as before: *remelted* pig-iron—cast iron; *remelted* steel of every description—cast steel. Here the division following the fluid or non-fluid state keeps the principal place; the hardening only the second. Therefore, all the members of the committee, differing in some points (Mr. Akerman and myself wishing a more detailed subdivision), agreed to this compromise without hesitation.

"It is asserted that such a compromise, comprising the languages of the principal iron-producing peoples, has not been necessary, and that each country may keep its own expressions without caring about others. But how can that be good and useful? I think every one, protectionist or free-trader, must be a friend of clear and distinct definitions, whether in treaties of commerce or in simple tariffs. And even besides this international question, is it not necessary for the public trade to have accurate definitions for every kind of ware, giving no room for intentional or unintentional deceptions?

"By the new nomenclature accepted and introduced, every tradesman and every customs officer who knows nothing about iron metallurgy easily distinguish:—I and II by the forgeability; C and D by the colour; A and B by the fracture—if necessary, by an easily made etching with acid; 1, 2, 3 and 4, by the hardening. Also, those ought to be satisfied who desire to examine the chemical properties, viz.:—

Iron.
- I. contains O 2, 3°° C.
  - 2 and 4; O·O, 6°° C.
  - 1 and 3; O, 6·2, 3°° C.
- II. contains 2, 3·5 ° C.
  - Amorphic C.
  - Graphitic and amorphic.

"But it is not necessary to make analyses and to dwell upon differences growing from the presence of other matters, which would be the case if you classify according to the amount of carbon.

"After having read all that has appeared in your *Bulletin* and the *Engineering and Mining Journal*, I have no hope that our nomenclature will be accepted in America. But, let me tell you, we are happier. It may be the interior value of the nomenclature, or it may be the authority of the names of the international committee that has accomplished this result, but what long discussion could not do is done. The nomenclature is accepted in Germany.

"The professors of iron metallurgy in Germany, Austria and Hungary have accepted it; the most widely circulated journal of mining and metallurgy and the official journal of the ministry of trade and commerce have accepted it; the Association for the Progress of Industry at Berlin and the Association of Miners and Smelters of Karntnen have accepted it. It will be introduced very probably in all official statistics. So we are certain that at least our rising generation will unanimously use the nomenclature proposed by the International committee.

"Well, you Americans will of course do what you think best, but please accept our German thanks, added to many thanks for the kind and amiable reception given us in your wonderful country, that you again have been the best help to a uniform nomenclature of iron in Germany.

"Very truly, DR. HERMANN WEDDING."

SCIENCE

HOMOGENEOUS IRON,

AND THE DEGREE OF HOMOGENEITY TO BE EXPECTED IN IRON PRODUCED BY VARIOUS SYSTEMS OF PUDDLING AND SUBSEQUENT WORKING.*

MANUFACTURERS of finished iron are frequently blamed by engineers for not giving them the exact qualities required, and they excuse themselves by saying that the pig-iron supplied to them under the same name varies very much in its composition, and that they cannot make an invariable product from it. Smelters affect to regard complaints of the quality of pig-iron as purely imaginary, but they themselves find fault with the minerals supplied to them, and mine-owners are very ready to tell them that they can only give such materials as the mines yield. Thus every one exonerates himself, yet the truth is that no one of the departments is without its difficulties; and if each, instead of ignoring those of the others, would patiently examine them, and endeavour to remove, mitigate or neutralise them, in the end all would be gainers. It is from such considerations that this paper is brought forward, in which it is the writer's intention to present some facts and offer some remarks from an ironmaker's point of view.

Words sometimes alter their signification so much in course of time that it is occasionally difficult, during the period of transition, to embrace all the shades of meaning current in any short definition; and if the title of this paper had been confined to "Homogeneous Iron," numerous precedents might have been found for a departure from the strict original sense of the term "homogeneous." But it is contended that many such departures give rise to ambiguity and confusion, and to a loss of valuable time which ought to be avoided. Thus the word "puddling" was originally restricted to the working of refined iron, which never became thoroughly liquid, but was in a "puddle" or pasty state throughout; and when unrefined pig began to be worked, and was found to melt thin and boil up freely from the rapid escape of carbon, the process was termed "boiling." But as the puddled iron was better than the boiled, there was the temptation to sink the word boiling altogether, and this has been done so completely that now, when we want to speak of the old puddling process—which is still carried on at all the best Yorkshire works and at many others where the very highest quality of iron is made—it requires a lengthy description to convey the intended meaning.

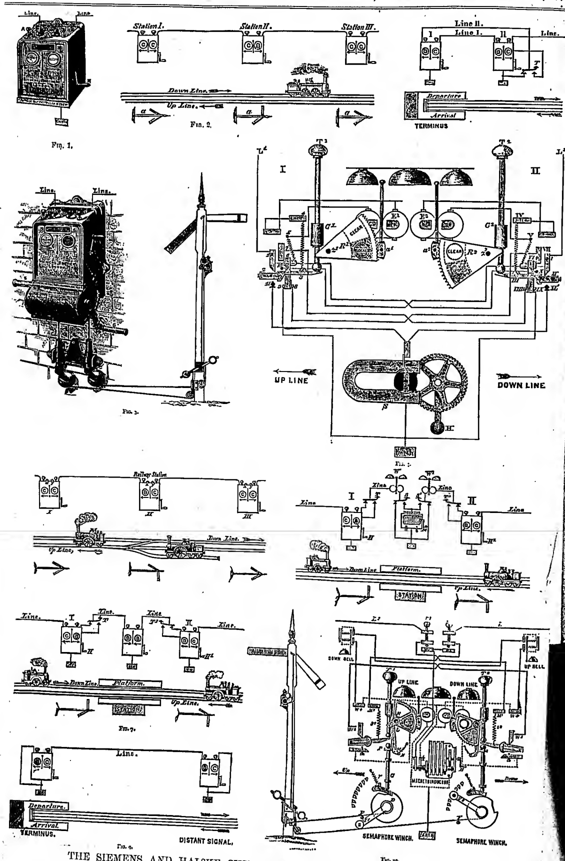
The term homogeneous seems to have been first applied to iron about twenty years ago, and it meant a comparatively pure iron manufactured by melting, too low in carbon to be called steel—in fact, presenting none of its characteristics. But within the last ten years makers of homogeneous iron have appropriated the term steel, steel being something better than iron; and now there appears in some quarters a disposition to adapt the word homogeneous to iron produced by puddling, whereas puddled iron is not, and perhaps cannot be made, truly homogeneous. It is highly probable that the use of the term steel has very much hindered the employment of true homogeneous iron in works of construction, for which it appears to be eminently fitted, by creating false impressions as to its hardness and the expense of working it, and it is a question whether the appropriation of the term homogeneous will help iron manufacturers nearly so much as the closest approximation to its most valuable properties which it is in their power to make. But here arises a difficulty: the finely crystalline appearance of such iron, when cut round with a chisel and broken suddenly off, finds little favour with engineers and consumers, while the fact of its being remarkably strong in its hot as well as in its cold state, and requiring a good deal of fire to heat and muscular force to work, excites prejudice on the part of those who have to expend their labour upon it.

The writer will now endeavour to show, first, what homogeneous iron is, and what are its properties; next, how far the conditions of various modes of puddling are compatible with the production of similar iron; and, lastly, how homogeneity is affected by the subsequent operations of hammering, rolling, heating, piling, &c.

Homogeneous iron will be considered herein as iron of the same kind or nature throughout, and consisting of similar parts. Thus iron may be homogeneous and yet contain all the elements usually associated with it, such as carbon, silicon, sulphur, phosphorus and manganese; but iron containing cinder cannot be truly homogeneous, because the nature of cinder is altogether different from that of iron, and in fact cinder does not combine with it at all, but only remains diffused throughout the mass. Iron produced by melting and casting into solid ingots, carefully heated and well worked, may properly be called homogeneous. Such iron has no right to the term steel when the carbon is not above 0·30 per cent., which is an amount sometimes exceeded in the very best brands of wrought-iron; for instance, an analysis of Swedish iron is given by Percy with 0·386 per cent. of carbon, and one of Russian with 0·34 per cent.

Homogeneous iron—or mild steel as it is now called—is remarkable, as compared with puddled iron, for its high degree of strength and ductility combined. This is well exemplified in the samples of mild steel and iron hoops of which tests are given in Table A. The pieces were about

* Prepared for the last General Meeting of the Society of Mechanical Engineers, at Birmingham, by Henry Kirk, Workington, and taken as read.



THE SIEMENS AND HALSKE SYSTEM OF ELECTRICAL RAILWAY SIGNALS.

ed on the voyage home 84 tons, the latter being Australian Bull-eye coal. Altogether the performance is an admirable one. The St. Osyth was built in 1874 by Messrs. C. Mitchell & Co., of Low Walker; she carries 4,000 tons dead weight, and her engines are 500 horse power nominal.

SIEMENS AND HALSKE'S ELECTRICAL RAILWAY SIGNALS.

In the improved form of block apparatus, a perspective view of which is shown at Fig. 1, the protecting case is entirely of iron, and may be put in communication with the earth for preventing any danger from lightning to the man working the apparatus. The handle, H, of the indicator is at the right hand side, and the two plungers, A and B, are at the top of the case. These plungers, or transmitting keys, serve as line-circuit closers, and when pressed down, produce the signal "line blocked" at the apparatus itself, thus sending the induction current to the preceding block station; the direction of the trains is marked by arrows. If the handle, H, of the instrument be turned, and at the same time the plunger A, on the left side of the instrument, be pressed down, the word "clear" becomes changed to "blocked," thus showing that the up-line is closed; and in the same way, if the plunger B were depressed, the right hand aperture would show that the down-line was blocked.

The signals given by electricity must be transferred to a standard signal visible to the engine driver, so that the signalman has not only to give the electrical signal, but also to work the visible standard signals. Let *a a a* (Fig. 2) represent these signals; when a train is proceeding on the down-line from station II. to station III., the signals should stand as shown in the engraving. If the apparatus were so constructed that a negligent signalman could omit to put his standard signal at "line blocked" after having given the electric signal, thereby clearing the preceding station, a collision might take place on the arrival of the succeeding train; but, as the man is unable to give the electric signal until he has put his semaphore at "danger," an accident is impossible, and delay only can ensue. The arrangement whereby a signalman is prevented from clearing the preceding block station before he has blocked the line with his semaphore, is shown at Fig. 3. In this case a winch is added to the bottom of the block apparatus, which may be placed in any convenient position inside the signal box, and this winch is so connected mechanically with the semaphore that, while the latter stands at "clear," it is impossible to give an electrical signal. By turning the handles S S, corresponding with the up and down lines, the semaphore arms are raised or lowered. In order to send an electrical signal to the preceding station (which is always the "clear" signal) it is necessary that the standard signal be first put to "danger," and no electrical "clear" signal sent to the preceding station during this "line blocked" position of the semaphore, not only blocks the electrical apparatus, but also interlocks the standard "blocked" signal, so that the standard "clear" signal can only be given after the electrical "blocked" signal has been changed into "clear" by the forward station.

The working of the electrical block apparatus is shown at Fig. 4, which represents two indices, identically the same for up and down lines, constituting one of the signalling instruments. To take No. 1, or that for the up-line, R_1, is a movable arm pivoted at 2_1, and provided with teeth on its periphery. The movement of this index up or down brings the words "blocked" or "clear" opposite the aperture in the case. The pallets of an escapement, a_1, similar to that used in clocks, engage in the teeth of the arm R_1. This escapement is attached to and worked by the polarized armature of an electro-magnet, E^1, and is caused to oscillate by a number of successive alternating positive and negative electrical currents. The arm, R^1, has, by its own weight, a tendency to fall, but, being held by the pallets of the escapement when they are at rest, it can only fall tooth by tooth when these pallets oscillate. As several alternating positive and negative currents in succession are required to give a number of oscillations sufficient to change the signal, an accidental current, a succession of currents of the same direction, or a discharge of atmospheric electricity, cannot change the signal. The armature connected to the escapement a^1 is polarized, so that the alternating positive and negative currents transmitted through the coils of the magnet E^1, cause it to oscillate. This oscillation, besides working the escapement, causes a hammer attached to the armature to strike the bells placed near it. To move the arm R^1 up again, a plunger, T^1, with a sliding weight, G^1, bearing upon the tail of the arm, is pressed down, thus giving the arm a tendency to rise as soon as the armature, a^1, oscillates. The plunger, T^1, also acts upon a commutator and determines the course the electrical currents have then to take.

The following example will serve to show the reciprocal operation between the block apparatus of two neighboring stations. In Fig. 4, the up-line is blocked, a train having just passed. As soon as that train passes the next station, the signalman then presses down his up line plunger, at the same time turning the handle of his magneto-inductor. By these two operations he blocks his up-line apparatus, and also sends alternate positive and negative currents along the line wire, L^1, and through the conducting parts marked 1, 2, 3, 4, to the coils of E^1, and thence through 5, 6, 7, *VIII.* and *IX.* to earth, thus causing the escapement, a^1, to oscillate. During this oscillation the arm R^1 descends, tooth by tooth, and brings before the aperture in the cover of the instrument the word "clear," while the word "blocked" becomes hidden behind the cover. A similar action takes place for the down-line indicator, marked II., when the currents are transmitted to L^2.

The apparatus above described, always interlocks with the standard signal, serves for block stations between railway stations where there are no points or sidings; it is also sufficient for small railway stations, but will require a few more manipulations for the blocking and clearing of the line when a goods or slow train has to be shunted, to allow an express or fast train to pass. At Fig. 5, *II.* shows a siding at a railway station, into which it is necessary to shunt a goods train to allow an express, one stage behind, to pass. When the goods train is shunted, the signalman at station *II.* blocks his up-line, thereby clearing station *III.* Before the express could pass station *III.*, its apparatus should show the signal "line clear." As this effect, when produced in the ordinary way, by turning the handle of the magneto-inductor and pressing down the corresponding plunger to "danger" at station *II.*, would involve the signal "line clear" at station *III.*, and so forbid the express to pass station *II.*, it becomes necessary to open the aperture at the top of the apparatus at station *II.*, and to change with the finger (without sending currents to station *III.*) the signal "blocked" to "clear." The block section between stations *II.* and *III.* still remain blocked; but, as soon as the express has passed station *I.*, this station, by blocking itself, electrically unblocks station *II.*, and allows the shunted goods train to proceed towards station *I.*, when the usual electrical connection between the three stations is again established.

If it be necessary for trains entering a station to receive a permissive signal at the entrance block station from the platform, the arrangement is adopted as shown at Fig. 6, where two trains are awaiting the "clear" signals which are to be sent from the platform to the entrance block station. In this case there is a magneto-inductor at the platform, and the two block stations, *I.* and *II.*, at either end; the block apparatus is of the usual construction, but has, in addition, the transmitting key, T, which, when pressed down while the handle, H, is turned at the same time, causes an alarm bell, W, to ring at the station platform, announcing the approach of a train. In order to answer the signal, the magneto-inductor at the platform is also provided with a transmitting key, S, the pressing down of which, while the handle, H, of the inductor is turned, clears the entrance block station, and allows the train to enter. As soon as the train has passed the entrance block station, the signal is again set to "blocked."

Should it be desired that the entering train be announced by a visible signal, as well as by the bell-signal, a block-signal apparatus is placed at the platform. In Fig. 7, which shows an arrangement for this purpose, the platform and both the entrance-instruments show "blocked." Let it be supposed that a train approaches the entrance block station *I.*, the signalman presses down the key, T, simultaneously turning the handle of his inductor, H, and thus rings a bell in the platform apparatus, thereby inquiring whether the down train may enter that station. If the platform is clear, a signal is sent back, ringing a bell at *I.*, and also changing the block signals at the entrance block station and at his own platform into "clear." As soon as the train has passed the entrance block station, *I.*, the signalman puts his standard signal at "danger," produces at his own apparatus the electric signal "line blocked," and at the same time clears the preceding station as usual, thus blocking his own again, and, as a proof for the station master that a train has passed the entrance block station, changing the "clear" signal into "blocked" at the station-master's instrument. Both signals are thus placed at "blocked" again, and remain so until another train approaches that entrance block station.

Fig. 8 shows an arrangement where the block signals begin at the platform of a terminus instead of at the entrance block station. In this case the entrance apparatus is connected with the section block apparatus by two line wires, the second wire leading to a key, T, at the entrance apparatus. All trains leaving the terminus are signalled as usual, and those entering are signalled as in the last case, an arrangement which gives the station-master entire control over the traffic. Block-signal apparatus may also be conveniently used as distant signals between platform and entrance block station, as shown at Fig. 9.

As the use of alternate magneto-electric currents for the production of the simultaneous audible and visible signals, "line clear" and "line blocked," is the important point as regards safety of Messrs. Siemens and Halske's block system, it may be mentioned incidentally that currents of this nature, uninfluenced by atmospheric electricity, are sent from one signal-box to another in a direction opposite to that in which the train is traveling; but it must not be forgotten that there is an accessory part of that block system which, whether working or not working, could not interfere with the safety, and which is actuated by the same induction machines which give the block signals, though independently. Experience has shown it to be useful to warn signalmen when a train has left the preceding block station and is traveling towards them. This information, though produced by the turning of the same induction-coil handle as that for blocking and unblocking the signals, is obtained by the lowering of a separate key, and its working might possibly be interfered with by strong atmospheric currents.

The arrangement for sending warning signals in a forward direction is shown at Fig. 10. P^1 and P^2 are the plungers or contact makers, the depression of which cuts either the up or the down index out of circuit and brings the line wire of either side into direct communication with the magneto-inductor. The latter is so constructed that, of the two currents produced at each revolution of the coil, only one is permitted to enter the line to obtain this result. The spindle of the revolving coil is for a short distance cut in half, one half being taken away and replaced by a piece of insulating material. One contact spring, *x*, is in communication with either terminal, p^1 or p^2, and receives the current produced during half the revolutions of the coil; that is, when the spring, *x*, bears against the metallic part of the spindle. The contact spring, *z*, is, however, in constant metallic contact with either line via the springs, s^1 or s^2, when the plungers, P^1 or P^2, are pressed down. The latter contact spring, *z*, therefore, communicates both currents to either line. The currents of like kind passing by the spring, *x*, cause a bell to sound at the forward block station, thereby warning the signalman of the approach of a train. By pressing down the plunger, P^1, these currents pass from the magneto-inductor into the up-line, L^1, and, by pressing down P^2, into the down-line, L^2. The course of the single currents being from earth through the magneto-inductor, *x*, p^1, P^1, L^1, to the forward stations into P^2, M^2, s^2, W^2, through coils of up-bell, W^2, through bobbin of down-line index to earth, the index will not be affected, but the bell will give any number of vibrations corresponding to the manipulation of the magneto-inductor.

As railway telegraph posts are, as a rule, already overloaded with wires, it is a matter of importance not to still further increase their burden; and in this respect, again, Messrs. Siemens & Halske's compares favorably with other systems, as the whole of the block signals for a double line, together with those for giving the intimation that a train has left the preceding block station, are worked by means of a single wire.—*Iron.*

19

[27080.]—Electric Bell.—In Vol. XXII. which you have, there are two separate ways how to make a telegraph instrument, and as for the bell, what could you want more than the article by Mr. Voll in the same Vol., Nos. 558 and 565? If the bell is only to ring once the wire will go to the magnet and back to battery. No platinum brake, &c., will be needed.—BLACKHEATH. 7/7

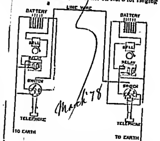
Improved District Telegraph Signal Box.

MR. S. D. FIELD, electrical engineer to the Electrical Construction and Maintenance Company, of San Francisco, Cal., has perfected and patented an improved signal box for District Telegraphs, which has been successfully introduced upon the District Telegraphs in California. June 77

Mr. Field's improvements, for which he has obtained letters patent, consist in providing the apparatus with an answering back signal, for the purpose of enabling the central office to indicate to the sender the receipt and understanding of the call. In each signal box there is a continuation of an alarm or sounding apparatus, consisting of a series of tripping levers, a trigger, and an alarm device, which are so arranged that the alarm can either be set by the act of transmitting a signal, or by an independent action, and afterwards be released by the operator at the central station by shunting a portion of the resistance in a line circuit, increasing the battery power, or reversing the line battery, so as to sound an alarm or signal at the particular box from which a signal has been received. The alarm is connected with the same wire over which is transmitted the signal from the signal box to the central station, but the inventor interposes in the same circuit an electro-magnet of low resistance that will not be affected by the electric current in ordinary use upon the line, so that signals can be transmitted over the line after the alarm is set without affecting the electro-magnet or alarm mechanism.

Another improvement made by Mr. Field is a means of correcting any mistake of the sender of the message, in case the pointer is turned to the wrong call. By a simple contrivance operated by a button, over the box, it is so arranged that in case the pointer is set at the wrong call, the sender, before sending the message, can press on the buttons and bring the pointer back to its place and then reset it properly before putting down the lever which sends the message.

[32312.]—Electric Bells.—I send an illustration showing "X. X." how he can connect his bells and telephones by one wire. He must use a relay, as shown. The switch has 3 knobs—Nos. 1, 2, and 3. The handles of both switches must be turned on No. 1 when not in use, waiting calls, both on No. 2 for telephonic messages, and either on No. 3 for ringing a



March '78

bell to call attention at the other end. I should imagine it would be better to alter your bell to single stroke (the connections make the difference), and the relay will make it continuous. I should make the relay of small size, and to fit in at the back of the switch. If you should not understand the relay, its action is thus:—When handle is turned on No. 3 right-hand switch a current of electricity is sent through wire to the other end, through No. 1 knob to electro-magnet in relay, which draws down the spring until it touches the other wire, which sends a current through the battery, and strikes the bell. I trust the other connections will explain themselves.—C. O. G.

THE AUTOMATIC FIRE BELL.—A correspondent of the *Globe* says that the automatic fire bell is by no means a new idea, as above twelve years ago an electrician fitted one up in his warehouse, which was so sensitive that an unusually hot afternoon was found to set it going. Sept 74

ELECTRO-MAGNETIC BURGLAR ALARM SAFE.

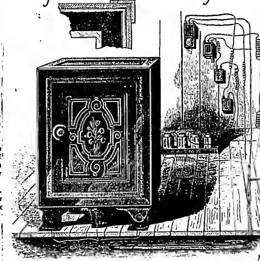
This invention, which is shown in the accompanying engraving, consists in a certain construction and arrangement of safes in connection with magnetic or electric wires, a battery and an alarm apparatus, by which the drilling, forcible breaking or opening as well as removal of safes is prevented.

The safe is constructed in such a way that it is impossible to tamper with it without it gives an alarm, either by drilling, forcible breaking, insertion of key, or by turning the knob of a combination lock, through which the c[...] the safe is connected with an inner insulating plate running on all sides and door thereof, or by moving the safe, which stands on plates inserted in the floor; the safe being moved from it will break the circuit of the current, connected with a relay, provided with an anchor, which will fall off, giving an alarm, as soon as the safe is moved, the same being the case if the wires should be cut connecting with the safe. The alarm thus brought into motion will keep on ringing until released, the alarm being provided with circuit breakers, which may be put to rest during the day. The alarm apparatus can be placed in any suitable place about the house, police station, night watchman's room, etc. The safe does not differ in appearance from any other. We are informed that this alarm can also be affixed to old safes.

The wires, which for convenience in the present case are connected with the front of the safe, will, in practice, be connected with the back, where they will be out of the way and out of sight.

This invention was recently patented by Mr. Max Koloseus, 123 East Houston street, New York, from whom further particulars may be obtained.

Fig. 2. Fig. 1.



ELECTRO-MAGNETIC BURGLAR ALARM SAFE.

ELECTRIC FIRE ALARM.

Close in the stall of M. D'Arlingcourt is that of M. Leblan, who shows one of the neatest automatic fire indicators we have ever seen. Before describing it, we may remind our readers that quite recently the system of fire alarms so successfully and so extensively adopted in America and in some parts of the Continent has been imported into London. The Exchange Telegraph Company in Cornhill shows some very good fire indicators, so sensitive that the change of temperature caused by the warm breath impinging on the instrument will set the bell ringing in connection with it. The apparatus which M. Leblan has devised is based upon the property which certain bodies, such as felt and wool, possess of acting as good conductors of heat when the heat rays vary by insensible degrees, while offering resistance to quick changes of temperature, as those caused by instantaneous combustion. M. Leblan is in fact the inventor of a new differential thermometer. In its construction he employs zinc, which is a metal having a high coefficient of expansion. The instrument consists of two strong plates of zinc cut from the same sheet and identical as to size, 0·6 meter long by 0·05 meter wide, placed parallel on a wooden pedestal; the ends on one side are firmly fixed, but on the other capable of moving freely. One of the plates is uncovered, and its end free to carry a platinum spring. A binding screw is placed opposite, fixed by an insulated body to the second one, which is covered throughout its length with a sheath of cloth or felt.

The screw is connected with one of the poles of a battery; the two plates are connected to the other pole, and in the circuit is placed a bell at some point where its sound can easily be heard by the inmates whenever it happens to be sounded. The action of this apparatus is easily seen. If the amount of heat received by the plates is gradual, the expansion of each is equal and the relative position of the platinum spring and contact screw is maintained; but should the development of heat be sudden, the uncovered plate expands at a greater rate than the other, forcing the spring against the screw, thus completing the circuit, when a current at once actuates the bell and gives the alarm.

[36127.]—Electric Bells.—Wind on each bobbin as much wire as will make it as thick a layer as the diameter of the core; this will give you a maximum of power. To lacquer the bells heat them so hot as to be too hot to hold, then chuck them and lacquer from centre to edge; binding screws are lacquered in the same manner. For the standard carrying bell either iron or brass will do; brass is the easiest to work. The wire can be wound from a bobbin fixed to back of lathe, and kept rather tight by means of a spring, so that the wire is pulled tight when being wound on, then close up to T have a rod hinged at the bottom with a fork, same height as bobbin, the rod being continued for about 1in., pass the wire through this into bobbin, and you will be able to wind any number of layers quite evenly. Electric bells may be made for any price. We make bells from 6s. 6d. to 60s. each, but of course, so much depends upon quality, that they could be made even at 3s. to 4s. each. I would not advise you to make common stuff. Vendors of rubbish have had a little day.—W. J. LANCASTER.

[36127.]—Electric Bells.—(1.) The amounts and sizes of silk covered wire to be used for making coils for electric bells are as follows:—The number of inches indicating the diameters of the respective gongs: for a 2in. gong, 8 yards of No. 26; 2½in., 9 yards No. 26; 3in., 10 yards No. 26; 3½in., 10 yards No. 26; 4in., 11 yards No. 24; 5in., 12 yards No. 22; 6in., 13 yards No. 20. (2.) The bells after being turned and polished receive an electro deposit of nickel or silver, or they may be warmed and lacquered with gold-lacquer in the lathe, screws and other brass fittings are done the same way. (3.) It is immaterial whether the bell support be of iron or brass. (4.) For winding the bobbins quickly and neatly have a steel spindle about ⅜in. diameter, fixed in two bearings on uprights on a stand. Cut two pieces of stout brass tube (⅜in. common tube) each one inch long, turn each one down taper to one end and put a set-screw in each. Then slide them over the ⅜in. spindle so that their thin ends are nearest together. Reels with holes of many different sizes can thus easily be fixed true and wound very easily either in the lathe or by hand by means of a small crank.—WIESENDANGER.

Jan 79

[35202.]—Electric Bells.—It is possible to ring two bells with only one wire by having two series of cells, but as this would involve much more expense and trouble than laying a double wire I should advise you to have the double wire and one series of cells.

You can work with one wire if you allow both bells to ring at the same time, and have a battery at each end, or you can so arrange the batteries and bells as to throw battery of one end in circuit with the bell of the other end, and so on, as per rough sketch,

where *a* represents the gas-pipe, *b*, line wire joined up with bells in circuit, *c* and *d* two wires going through cells and on to pushes in connection with line wire. Thus, when either of the pushes are closed down the battery and distant bell are in circuit, and vice versa. But as I said before you would require two series of cells.—W. J. LANCASTER.

[35202.]—Electric Bells.—I think the subjoined arrangement is simple, and will meet "Edward's" requirements:—Let A and B be the bells at shop and house respectively—connect the line wire with

a binding-screw of each bell, as shown. Have a battery at shop and another at house, C and D; connect line-wire also with one pole of each battery; connect the remaining binding screw of each bell with a metallic plate, P and N; connect the remaining poles of batteries, each with metallic plate, R and S. Instead of the ordinary "push" arrange metallic springs at shop and house, as shown at H and K, each permanently connected with gas-pipe, and so placed that when at rest they are in contact with the plates, P and N, respectively. Let the plates, R and S, be so placed that the springs, H and K, when pressed, come into contact with them. It will readily be seen that on pressing the spring, K, the bell, B, is thrown out of circuit, and the battery, C, is thrown into action, ringing the bell, A. Similarly pressure upon the spring, H, throws A out of connection, and by means of the battery D rings it. I have not had much experience with the telephone or electric light, but for electric bells I have been well pleased with No. 20 copper wire, covered with cotton and saturated with paraffin wax. For bells I have been most satisfied with the Leclanché battery.—AMPHIBIAN.

IMPROVED ELECTRIC BELLS.

We have had our attention directed by Messrs. F. Darlon & Co., 48, St. John Street, West Smithfield, to their new improved continuous-action bell. The advantage of this over the ordinary bell is that it continues ringing after the door or window is closed, and even when the wires themselves are cut. This appears a great advantage over the old form, as in many cases burglars cut the wires, and so prevent an alarm being effective. In this bell the electric current, passing through the wire, causes a spring to be detached, and thereby places it in short circuit, thus preventing the cutting of the main wire from interfering with the action of the bell.

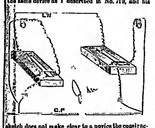
April 78

[35202.]—Electric Bells.—If "Edward" requires to ring the bell in one direction only at one time he can readily do so with but one battery and one line wire, according to the following plan. A is the

Jan 79

battery, placed, say, in the house. At P and Q are two small levers, which can be moved so as to put the line wire, L, and the short wire, M, which constitute the poles of the battery, in connection with the earth in two sets of ways. The figure shows the connection in case "Edward" wishes to ring the house bell from the shop. Before leaving the house he brings the lever, P, in connection with the wire which traverses the electro-magnet of the house bell; thus M is brought into connection with the earth at E. Whenever, then, in the shop he presses down the lever, Q, in direction of the arrow he completes the circuit, and the house bell rings. Before leaving the shop he must raise the lever, Q, so as to bring the shop bell into the circuit, and when he returns to the house he can complete the circuit, and cause the shop bell to ring every time he presses down the lever, P.—W. P. H.

[35202.]—Electric Bells.—I think something must be wrong with Mr. Lancaster's sketch on page 452, January 10, No. 720. As shown, when contact is made, both bells are in circuit, and most of the current would go through the near bell, and a portion only (inversely proportional to resistance) through the far bell. "Amphibian" has illustrated the same device as I described in No. 719, and his



Jan

sketch does not make clear to a novice the construction of the signalling key. I send a sketch to illustrate my former answer, which the Editor can put in if he thinks enough has not been said.—PLONT ALMONT.

LA BLANC'S FIRE TELL-TALE.—This ingenious fire alarm (for an account of which we are indebted to *Engineering*) is designed to indicate outbreaks of fire on premises. It is so constructed as to be sensitive to sudden rises of temperature, while it is unaffected by slow variations of the same. The sensitive part consists of two expansible plates of sheet zinc about 60 centimetres long and 0·25 centimetres thick, cut from the same piece so as to be isometric, or having an equal expansion. They are doubled into a gutter shape, so as to be more tight, and are fixed at one end, while being free to expand at the other. One of these is swathed in flannel, and the other is bare to the atmosphere. When the variations of the temperature in the apartment where the tell-tale is placed are sluggish, the flannel round the covered plate will not interfere with its expansion; and both plates, naked and clothed, will expand equally. But when there is a sudden rise of temperature the bared plate will expand the faster. The effect of this is to make it bring a contact screw which it carries into contact with a spring contact carried by the plate, and the circuit being closed an alarm bell is rung.

Jan 79

ELECTRICITY IN CHINA.—On Tuesday, 1st Oct., we were entertained with a grand display of torpedoes at "Haiku," near Tientsin, being the annual inspection of the students of the Imperial Torpedo College by H. E. Li Hung-chang. A straight reach of the main river was selected, about a mile in length, and all boat traffic stopped for the day. The students had been busy for two or three previous days laying down cables, joining up torpedoes, &c; and when H. E. arrived at the appointed time many thousands of spectators had assembled on the banks and house tops commanding a view of the situation. The work carried out was a representation on a minor scale of the defence of the channel at Taku. A chart was drawn out, showing the position of each torpedo, and they were fired in the order given by H. E., at the sounding of a bugle. As the last notes of the bugle died away the first charge exploded, throwing up an immense column of water in the air, to the height of three or four hundred feet; this was immediately followed by five other explosions, forming the outer line of defence. On the next word of command, seven torpedoes were simultaneously fired, throwing up a tremendous body of water and shaking the place as by an earthquake; these were followed by seven torpedoes fired singly; after which contact torpedoes were shown, in which heavy charges of powder were exploded, by a steam-launch striking the circuit-closer moored in mid-stream. The experiments were concluded by an array of five torpedo boats advancing in line, each armed with two fifty-pound spar torpedoes, which wheeling round a flag representing an imaginary enemy's ship, launched their torpedoes and fired at a given signal. The boats rose with the upheaving

JANUARY 15, 1879.] THE TELEGRA

stream, and were instantly hidden from view by the large volume of water thrown up.

H. E. the Viceroy congratulated Mr. Betts warmly upon the success of the experiments; and calling up the students of the college awarded official rank to several of them and prizes to all, but as each one of the forty-nine torpedoes fired was the work of one individual student, it was difficult to draw a distinction where all were alike successful. H. E. returned to the Yamên at 6 p.m. Now that the inspection is over, the students will at once commence the erection of the Tientsin-Taku telegraph, and the survey for the Tientsin-Paouting-foo-Peking line will be carried out.—*North China Daily News*, Oct. 9, 1878.

WE have to record the death of Sarah Faraday, widow of Michael Faraday.

FLOOD TELL-TALE.—We learn from the *Moniteur Scientifique* that a new contrivance, invented by U. Camille Gras, for warning towns on the lower reaches of a river of the water level of its upper stream, has recently been tried with success between Laroque-Bouillac and Capdenac, on the river Lot. It consists of a float moored on the surface of the river, and an electric indicator, actuated by the float in such a manner that the needle follows the level of the stream. Indicators may be placed at distant towns, and connected to the float by telegraph. When the river reaches a certain flood level, an alarm bell is rung at these towns, and preparations may be taken against the coming flood.

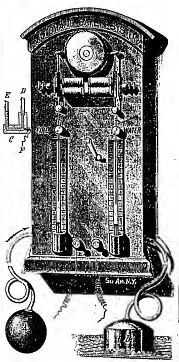
Jan 79

A SIMPLE ELECTRIC ALARUM.

[15138.]—LETTER 15346, p. 564, rather amused me. May I be permitted to point out to Mr. G. H. Mason that in the MECHANIC of Dec. 6th, 1878, p. 327, Letter 34122, I gave a sketch of an electric alarum, making the very same connections as he has, to place the clock in circuit with the bell and battery? Besides which, my arrangement is much more simple than his, as, in mine, all that is necessary is a simple piece of wire, which is bent and placed against the clock dial, at whatever time the hour hand of the clock is required to come in contact with it, and the hand *carries the wire round with it*; whereas, in Mr. Mason's adaptation, without the pointer, it is released directly the bell begins to ring, it will either spoil, or at least stop, the clock. Besides all this, in my plan it is not necessary to shorten the minute hand of the clock, a process of mutilation which I should think few people would approve. Mechanician.

FIRE AND WATER INDICATOR.

We illustrate herewith a novel fire and water indicator and alarm, which is the invention of Col. A. Gerard. It was



AUTOMATIC SAFETY APPARATUS.

recently patented in this country, also in Canada and Europe, and is controlled by the Automatic Safety Company, of No. 40 Charles St., New Orleans, La.

The invention consists in a simple arrangement of devices, by means of which the presence of fire or undue heat or any change of temperature may be indicated or recorded at any distant point. The instrument illustrated is also designed for the detection of the presence of water in the holds of vessels.

The two vertical glass tubes shown below the alarm apparatus, and marked "Fire" and "Water," are similar in their construction. The glass tube, D, is inserted in a metallic piece, C, which extends through the support, and has a passage, E, that communicates, in the case of the fire alarm, with the receiver hollow sphere, A, and in case of the water alarm with the bell or receiver, B, which is inverted upon the floor or surface liable to the incursions of water. Needles enter the tops of the glass tubes and extend downward toward the mercury contained in the lower part of the tubes. These needles are in electrical communication with the alarm bell at the top of the apparatus, and the mercury is in communication with the battery wires, the whole being arranged so that the rising of the mercury beyond the prescribed distance in either tube will complete an electrical circuit and operate the alarm apparatus.

The hollow sphere, A, being placed in any distant apartment, a rise of temperature in the vicinity of the sphere expands the air contained by it, creating a pressure which displaces the mercury in the tubes of the apparatus and gives the alarm. Similarly, when the water rises upon the surface on which rests the bell, B, the air in the bell is displaced, and the mercury in the tube marked "water" rises and completes the electrical circuit and gives the alarm.

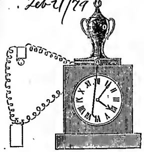
The necessity of an invention that will with certainty report leakages or fires on shipboard will be recognized by any one having even a cursory knowledge of shipping, and the simplicity and adaptability of the Gerard system will be apparent to our readers.

This apparatus is applicable to buildings as an indicator of high temperatures or fire, and, placed in a cellar liable to flooding, it indicates the presence of water. It is capable of many other applications, which our space will not permit us to enumerate.

A SIMPLE ELECTRIC ALARUM.

[15396.]—ALTHOUGH electric alarums are not strangers to your pages, I am not aware of having seen so simple an arrangement as that which I venture to introduce to your readers. All that is necessary to transform any common clock into an alarum in connection with an electric bell is, to connect one pole of the battery with the works of the clock (by attaching the wire to one of the screws connected therewith), and the wire from the other pole (having the bell attached) to a movable pointer, whose extremity is capable of different positions on the dial. The first point is easy enough. To accomplish the second: take a flat piece of mahogany or deal, the size of the top of your clock and about ½in. thick; into the side of this piece of wood, A, fix a binding screw, B. To the base of the binding screw (B) attach the wire from your bell, and fasten it to block A. The block may now be placed on the top of the clock and kept in

Feb 21/79



position by an ornament, O. For the pointer bend a knitting-needle (or, better still, a piece of stout brass wire) into the shape represented by P (Fig. 3). Clamp this in the binding screw, B (shown in position).

Now cut the minute hand of the clock, so as to make it shorter than the hour hand.

If you wish to wake at six, clamp the pointer so that the point will be touched as the *hour* hand comes round to six o'clock. Communication between the poles will thus be effected, and the bell will ring until you unclamp the pointer. This, at any rate, insures your getting up, and lessens the risk of taking a second "nap," as often happens with some kinds of alarum. Of course, I am supposing the dial to be a non-conductor, such as enamel or paint.

If the clock be not flat at the top, the block and pointer could be placed beneath the clock.

Geo. H. Mason.

BRIGHT'S ELECTRICAL FIRE INDICATOR.

THE electrical fire alarm systems so common in American towns, have never been received with much favour in England. Whether this arises from mere apathy or from the conservatism for which

Local Government Boards are notorious, it is difficult to say, but the fact remains that although many attempts have been made, but very little, if any, progress has resulted towards introducing any system of electrical or other fire alarms. It is not that such systems have not been shown to be practicable, for many have been exhibited and partially worked with success, but unfortunately, we believe, in no case, where the apparatus has been fitted, has an opportunity arisen for practically demonstrating the utility of the inventions, and for this reason possibly the schemes have been allowed to fall into oblivion.

One of the most recent inventions for effecting the object in view, is that of Mr. E. B. Bright, whose system has recently been fitted up, and had a practical trial, in Glasgow. As this system possesses some decided points of novelty over those hitherto invented, it merits a description.

The chief point of novelty in the apparatus consists in the employment of artificial electrical measures of resistance (or rheostats) for the purpose of making known the locality of the fire; such artificial measures of electrical resistance being used in combination with thermostats or appliances for closing or opening or making a variation in an electrical circuit or circuits by such fire.

The following is a description of the apparatus:—

Fig. 1 is a section, and fig. 2 a side view of a thermostat, consisting of a metallic box inside of which is fixed a curved band *c*, formed of two metals, such as platinum and brass, which expand unequally under the influence of heat. Opposite the end of the band *c*, is an insulated screw *d*, which can be so adjusted that the addition of any given amount of heat will, by its effect upon the band, bring the end of the band *c* into contact with the end of the screw terminal *d*. The terminal *e* is connected with the metallic box, and therefore with the curved band *c*.

Fig. 3 is a general plan, shewing the apparatus employed at the fire brigade station or other place to which a warning is to be given, and also a diagram of the electrical circuits in connection with the thermostats and rheostats by which the locality whence the warning proceeds is indicated.

Fig. 4 is a side view of the indicating apparatus at the fire brigade station or other place to which a warning is to be given.

The series of circles marked with numbers varying from 5 to 15 included by the bracket *f*, represents a number of rheostats placed in the various buildings or places from which an alarm may be given. They are connected together by a line wire *g*, extending to the fire brigade station, as shewn by the diagram, which wire is there joined to one side of the differential coil *h*, and thence through the alarum *i* to one pole of the battery *j*. The same pole of the battery *j* is also connected through the alarum, to the other side of the differential coil *h*, and thence to the end of a series of rheostats fixed round a circle in the indicating apparatus at the station, which are also marked on the plan, with numbers varying from 5 to 15, indicating electrical resistances corresponding with those of the rheostats included in the bracket *f*, before described.

By means of the handle *k* the arm *l* with a spring *m* can be moved over a series of metallic plates *n*, *n*,

2 26

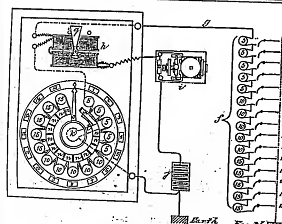


FIG. 3.

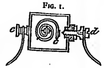

FIG. 1.

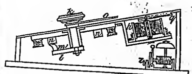

Fig. 4.

FIG. 2.

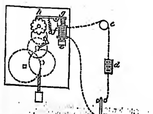

FIG. 5.

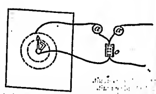

FIG. 6.

27

which are insulated from each other, and connected consecutively with tho rheostats, as shown on tho plan. Tho arm *l* and spring *m* are connected with tho other pole of tho battery *j*, which is also connected to tho earth. To the handle *k* is attached a pointer *o*, moving outside tho dial of tho instrument over a circle of figures corresponding to tho number of rheostats in the circuit.

Connected to one end of each of the rheostats included in bracket *f*, is a thermostat, the insulated screw of which *d* (figs. 1 and 2), is connected to tho earth. On an undue increase of heat taking place, the band *c* (figs. 1 and 2) of tho thermostat makes contact with tho insulated screw *d* (figs. 1 and 2), and thus completes the circuit with the battery *j*, as shewn by the dotted line *p*.

The electric current from the battery *j* passing thus through the alarum *i* rings it, and also passing through one side of tho differential coil *h*, deflects the disc *g*, which is fixed to the axle of a permanent magnet contained within the coil *h*. On the alarm being thus given, the person summoned moves the handle *k* round the dial of tho instrument, and as soon as tho spring *m* comes into contact with the particular plate *n* connected with the rheostat that corresponds with the line rheostat which has been put to earth by the thermostat at the point from which tho alarm is given, tho electrical balance of tho differential coil *h* is re-established, and tho disc *g* returns to zero.

Tho pointer *o* indicates tho number on tho dial of the station instrument which corresponds with tho number of the place on tho station list from which tho alarm emanates.

In the plan of tho apparatus, as drawn in figs. 3, 4, and 5, only fifteen protected places are shewn, but a larger or smaller number can, of course, be connected.

Figs. 5 and 6 shew a train of clockwork brought into action by a differential relay, which moves round tho contact maker in connection with the station rheostats in case of fire, until the balance between the station rheostats and the line rheostats is re-established, when the indicating hand attached to the axle of the contact maker (as in the apparatus worked by hand shown at fig. 3) points to the number showing the locality of the fire. In this figure *a*, a^1, are the differential coils of tho relay; *b* is tho contact maker influenced by them; *c* is the battery of tho line and station circuit, and *d* the battery of the local relay circuit; *e* is the coil of the alarum, and *f* is an electro-magnet actuating an armature *g*, and thus releasing tho escapement or detent h^1.

ap.-79

FIELD TELEGRAPHS.—Lord Chelmsford has asked for a field telegraph to be sent out to him; also electric lights for his encampments. The Ordnance Department at Woolwich have accordingly forwarded a fully equipped wire-waggon-and-barrow apparatus to the *Loanda*, now taking in cargo at the Royal Arsenal. The waggon consists of a strong but simple framework on ordinary wheels, supporting on revolving spindles six drums or reels of telegraphic wire, the movement of a lever and clutch causing the vehicle either to lay or pick up the wire as it passes over the ground. The barrow carries a single drum, and is mounted on wheels only a ft. high, with a 2 ft. track. It resembles an ordinary hose-reel, and is so light that it can be run over the field by one or two men, and can, therefore be of use during an action. Each drum carries 133 lbs. of wire. The waggon carries telegraph poles, a ladder and tools for constructing an "air line." The poles consist of iron tubes, in lengths of about ten feet, uniting by a bayonet joint and secured by three guy lines. A few sets of electric lighting apparatus and portable engines will also be sent out. The force under his command does not seem even to have been provided with Mance heliographs.

[37215.]—Electric Bells.—The bells may be turned in the usual way, and faced as true as the turning tool will leave them, then with a smooth file followed by emery paper a good surface is obtained; and if you like you may use the burnisher, but this makes the work common in appearance; the better way is to polish with a piece of thick cloth, oil, and rottenstone, then lacquer with either pale gold or gold lacquer, or if you silver the bells the lacquer should be quite colourless. The bronzed work should be done with bichloride of platinum for good work, then blackleaded and lacquered with colourless lacquer.—W. J. LANCASTER.

[37216.]—Science Examination.—Gentle[illegible]

78

The Underground Telegraphs in Germany.

[Berlin correspondence of the London Times.]

The Reichstag has voted the sum of 1,830,000 marks for the further construction of subterranean telegraph wires. Germany will soon be intersected with a complete net-work of this invisible and inaccessible means of communication, which no thunder storm can destroy and no roving enemy can readily cut. In 1876 it was first proposed to connect by underground cables all the chief centers of commerce and industry in the Empire, all the fortresses and places of arms, the cost being reckoned at about 31,000,000 marks (£1,700,000). The first experiment of the kind was made by the sinking of a wire between Berlin and Halle, which has been subjected to the strictest scientific tests, and yielded highly satisfactory results, not a single interruption being recorded. When the whole work is ended the German Empire will be crossed by two great main cables, stretching from Königsberg, in the north, to Strasburg, in the south, and from Hamburg, in the northwest, to Ratisbon, in the southeast, intersecting at Berlin. Strasburg will also be connected with Metz. In addition, another sunken wire will curve away up from Strasburg through Cologne to Hamburg, while Ratisbon and Königsberg will similarly be connected. An underground wire will also bind together Berlin, Dresden, Stuttgart and Munich, communicating with a fifth main cable passing through South Germany. In three years, it is said, the whole network thus planned by Dr. Stephan, the Postmaster General, will be completed. The half is already finished. An underground cable now connects Berlin, Halle, Leipsic, Cassel, Frankfort, Mayence, Mannheim, Carlsruhe, Rastatt and Strasburg; another line runs from Berlin, through Magdeburg, Brunswick, Hanover, Münster, Düsseldorf and Barmen-Elberfeld to Cologne, while Berlin and Hamburg are also connected, throwing out branch lines to Kiel and Cuxhaven, to Bremen and Emden, thus joining the North Sea cable communicating with England and America. A sum of 18,000,000 marks (£900,000) has already been spent on this subterranean enterprise, and the money now voted will be employed in connecting the towns and harbors along the Baltic shore for the furtherance of commerce and coast defense—a work, said the Postmaster General, which should be proceeded with as speedily as possible.

A fire-telegraph system, with fifty-eight kilometres of line, is now established at Munich. The wire used is patent cast steel from Cologne, mostly 3·1 mm. in diameter, and stretched over the houses in spans of not more than 200 metres. The lines over the houses are found much less liable to disturbance than those fixed to the fronts of houses. A thoroughly organized system of

May 79

MECHANIC AND WORLD OF SCIENCE

defence against fire is in operation at the extensive steel works of Krupp, at Essen.

Thomas Alvah Edison and George Harrington against the Western Union Telegraph Company.

This case, which is an application on the part of the plaintiffs for an injunction against the Western Union Telegraph Company, restraining the latter from the use of the duplex and quadruplex telegraph transmitters, which Edison invented in 1873, was argued in the District Supreme Court, at Washington, before Judge James, on the plea of the defendants, Feb. 27th. Messrs. J. H. Ashford and Matt. H. Carpenter appeared in support of the plea, and Messrs. J. H. B. Latrobe and B. D. Massey for the bill. The former argued that the pendency of a similar suit in the United States Circuit Court at New York barred the one at Washington, and counsel for Edison that the two suits were compatible, being for infringements of his patents in different places. The suit arises from Edison's having contracted to sell the patent for $15,000 and $233 royalty on each circuit to the company, on which he received $5,000 on account, and afterward, discovering that, in a partnership which he had concluded with Harrington, in 1870, he had agreed not to sell his inventions without the latter's consent. The company had, in the mean time, put the transmitters into use, and retained them, announcing their readiness to perform the contract. The Court took the papers and reserved its decision, after giving the defendants leave to file the record of the New York suit in this case.

THE HALL AUTOMATIC ELECTRIC RAILROAD SIGNALS.*

The "block system" has been generally acknowledged by competent authorities as the safest system for working railroad signals and conducting traffic. Notwithstanding this fact, it is used to only a very limited extent on even our busiest railroads.

If we inquire into the reason for this, we shall find that it is largely due to the imperfection of most of the appliances which are used in operating this system, and that they do not completely eliminate errors and thus make it practically infallible. Late improvements in these appliances—such as the apparatus of Messrs. Saxby and Farmer, known as the "union of the block and interlocking systems" and the "electro-semaphores" used on some of the French railroads, have contributed greatly toward perfection, and thus, it is thought, should have overcome the objection to the introduction of the block system.

There is, however, still another and probably even stronger

* Abstracted from the *American Railroad Gazette*.

objection, which is purely economical. New appliances require an outlay of capital; and the cost of maintaining and operating them would swell considerably the working expenses of a railroad. It is this last expense to which the managers of our roads are mostly averse. In Europe the great number of watchmen employed on railroads—as, for instance, in France, in connection with electro-semaphores—are advantageously used to attend to the signals also; but the small number of *employés* of this class on our roads would make it necessary to engage new men for this work.

We will not discuss here whether this extra expense would be repaid in the end, but attention will be called to the efforts of American inventors to avoid this obstacle in the progress of the system by devising such appliances as will act automatically without the intervention of attendants.

Such automatic signals, invented by Mr. Thos. S. Hall, are already in operation on some of the New England railroads. They combine the block with the interlocking system, and have been worked out with remarkable inventive skill.

The manner in which they are operated being different from that of other signals purporting to have the same object, it needs to be understood before the mechanism of the apparatus can be clearly comprehended. Each line is divided into sections, at the entrance of which are erected two signals, one called the "danger signal," and the other the "safety signal." These signals are of the disc form, visible when displayed through circular openings made in boxes in which they are enclosed. They are placed on posts of sufficient height to be conspicuous. The "danger signal" is placed immediately at the entrance to a section, and the "safety signal" some 1,000 feet further. The disc of the first is red, and that of the second is blue; but this difference is not essential to the system, and both of them can be of the same colour. From the difference in names of the two signals, it should not be concluded that the one when displayed means *danger*, while the other when displayed means *safety*, as either of them in this position is the signal of danger, and thus stops the advance of a train. The name of "safety signal" was given to the one because it gives the means of a constant control of the working order of the apparatus, which must be observed by the locomotive driver. Any derangement of the signals, being thus easily discovered by the first train passing, would be reported at the nearest station—the train having passed over the section cautiously—and the damage could be speedily repaired.

The signals are acted on by electric currents, being connected by wires with a battery. At all times, when one of the two signals is displayed, the other is hidden from view—the change of the position of one of the signals causing the reversal of the other. The way in which this is effected will be described below.

An examination of the system will show that the signals, say, at C and D on the "up line," and at M and N on the "down line," have their "danger signals" hidden, and the "safety signals" displayed. This position of the signals indicates that the corresponding sections are not occupied, and that trains may therefore run over them. The signals at B have just the reverse position, in consequence of the section B C being occupied by a train. If a train on the section A B were now to arrive at B, it would find that the "danger signal"—which is the first which would be seen—was displayed, and thus the section B C would be blocked. But the first train, which then occupies the section B C, arriving at C, finds the "danger signal" hidden from view; it therefore advances and enters the section C D. At the moment when the train enters this new section, the following action occurs: The "danger signal" at C displays itself, and the change of its position causes a change of position of the "safety signal." The train arriving next in sight of the "safety signal," and finding it hidden from view, does not stop, but proceeds further. This position of the "safety signal" indicates to the engineman that the "danger signal" behind him has been displayed to protect his train. Should he, however, find the "safety signal" displayed on his approach to it, he would know that something was wrong with the apparatus, and would proceed cautiously over this section, reporting the derangement at the nearest station.

This reversal of the signals is effected by means of an electric current, closed by the action of a wheel of the passing train which depresses a lever of a "track-instrument." This track-instrument is placed in close proximity to the "danger-signal." Although the train has entered the section C D the section B C remains still closed by the undisturbed position of the signals at B, and it is not until the train reaches a second track-instrument, which is placed about 1,600 feet from C, that a circuit acting on the signals at B reverses their position, and thus opens the section B C for traffic.

It will be noted here that the train is already well protected by the signals from the rear, when the section behind is opened for a succeeding train.

The same operation continues along the whole line as the train proceeds from section to section.

Hall's signals can easily be applied to a depôt which possesses several switches, side and cross-over tracks, and a roadway crossing. On either track, about a mile each way from the station, is seen a track instrument marked "Strikes bell at road crossing." A train passing over one of these instruments closes a circuit which strikes an electric bell at the watchman's house at the road crossing, notifying the watchman of the approach of a train, and he then closes the roadway against ordinary traffic. The use of the locomotive steam whistle is thus replaced by an electric bell. The approach to the depôt is protected by two distant signals, the "danger" and the "safety signals," in exactly the same manner as the entrance to a block section on the open road, as described above. But, it being advisable that the station agent and the passengers be notified in time of the approach of a train, the reversal of the signals from *safety* to *danger* causes an electric bell, placed at the station, to strike. Each line has a separate bell. These bells, being of distinctive tones, indicate also the directions from which the trains approach. This is another instance of the suppression of the use of the steam whistle.

The track instruments which open the way to the depôt are, placed at the other extremities of the depôt, as shown in the plan.

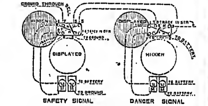
To enable the station agent to operate the distant signals from the station—the necessity of which may sometimes arise, as, for instance, when the passengers are crossing the "up line" to take the "down line" train, in which case the "up line" should be closed—a hand instrument is placed there, with which the signals can be set either at *danger* or *safety*. The instrument is locked, and the key of it is in the possession of the agent.

The switches are interlocked with the distant signals, by means of "switch instruments," in such manner that whenever a switch is set wrong to one of the main lines, the respective signals will display *danger*—if they were not previously in that position—and remain so, unaffected either by the track or the hand instrument, until the switch is set back for the main line, when the signals will be set automatically to safety. Should a switch be placed at a long distance behind the station, in order not to prevent a train from approaching the station, a special switch signal, operated by the instrument of this distant switch, may be erected.

The diagram shows the connection of wires of the two signals, "safety" and "danger," which constitute one signal post. The disc of the "danger" signal is shown displayed, while the disc of the "safety" signal is hidden (both being, however, in the raised position). Such position of the signals indicates that the section of the road which is guarded by them, is occupied by a train. The signals remain in this position until the train passes over a track instrument.

Every track instrument connects the "ground wire" with the signal apparatus; but that track instrument which *opens* a section connects with the "safety signal" apparatus—namely, with its connector, 2 (see Fig. 1), and that track instrument which *closes* a section connects with the "danger signal" apparatus—namely, with its connector.

FIG. 1.



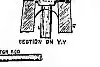
If, therefore, in the position of signals shown in the diagram, the train passes over a track instrument that *opens* a section, an electric current is closed which runs from the ground through the track instrument, the safety signal—namely, its connector 2, circuit-closer H, connector 1, electro-magnet N N, and hence through the battery to the ground again, or *vice versâ*. (The connection of wires is indicated in the diagram with dotted lines.) As the electro-magnet, N N, becomes magnetised, it produces a fall of the "safety signal" discs which will then take the displayed position shown in dotted lines. At the same time the circuit-closer, H, will swing, or switch off, from the position indicated by a full line into the position H', shown by a broken line, which change of position will break the circuit between the connectors 2 and 1, destroying the vitality of the electro-magnet N N. The action of the electro-magnet is thus momentary, and as soon as the stroke of one wheel of a train on the "track instrument" has produced the change, all subsequent strokes are without effect; hence, that portion of the apparatus which contains the circuit-closer H has been called by the inventor the "cut-out." At the same time that this is accomplished, the spring circuit-closer, T, of the "safety-signal," by the action of a finger, P, closes another current, which runs from the ground through connector 6, the circuit-closer T, connector 5, to the danger signal, namely, through its connector 2, circuit-closer H, connector 1, to the electro-magnet N N, and thence through the battery to the ground again, or *vice versâ*. This circuit causes the fall of the disc of the "danger" signal, in which position it is hidden. The circuit-closer H of the "danger" signal will then take the position shown by the dotted line, breaking the circuit, but producing no other effect. The position of both the signals will thus be reversed and the section will be opened for traffic. If a train should now enter upon this section, the track instrument which *closes* the section would be struck by the wheel, and cause a current to pass from the ground through the track instrument to the "danger signal," namely, through its connector 3, the circuit-closer in the position H', connector 4, to the electro-magnet M M, and thence through the battery to the ground again, or *vice versâ*. This would cause the disc of the danger-signal to rise again in the displayed position, and the circuit-closer to take the position shown at H. As soon as this is accomplished the spring-circuit-closer T of the "danger signal" would close momentarily, completing a circuit that passes from the battery through connector 6, circuit-closer T, connector 5, to the connector 3 of the "safety signal," then through its circuit-closer in the position H' to connector 4, then to the electro-magnet M M, and thence through the ground to the battery again. The disc of the "safety" signal will rise, therefore, into its hidden position. The section of the road will thus be closed again for traffic until the operation described at first is repeated.

If the signals belong to a depôt section, the apparatus of the safety signal is provided with another spring circuit-closer, T', which, when the disc rises, is closed and completes a circuit passing from battery through connector 8, circuit-closer T', connector 7, and thence through a bell (placed at the station) and the ground to the battery again, or *vice versâ*. Thus the approach of a train is announced at the station. In this manner the signals are operated by the movements of the trains themselves.

The switch interlocking instrument consists of a lever, L, pivoted at P P in a casting, G, the lower portion of which is shown broken off, but which resembles the casting of the track instrument, and is likewise bolted to a cross-tie of the road. The lower end of the lever is connected with the switch-rails by a rod in such manner that when the switch is being moved the lever L swings on its pivot, taking a position indicated by the centre lines *l l* or *l' l'*, Fig. 2. While the switch is set for the main line the lever L has the vertical position, as shown in the engraving. The upper end of the lever is provided with two cams, *b* and *b'* (Fig. 2). The casting G has on its top a cover, C, on which are attached two insulating wooden blocks, A and B, carrying six metallic plates with connectors, marked 1 to 6. Three spring circuit-closers, *a*, *c*, *e*, serve to effect closures, or a breaking-off of the electric currents between the connectors; the circuit-closer *a*, between connectors 1 and 2, the circuit-closer *c*, between connectors 3 and 4, and the circuit-closer *e*, between connectors 5 and 6. They are operated by means of the following mechanism, and in the following manner:—

FIG. 2.

FIG. 3



Between the circuit-closers *c* and *e*, in the centre of the machine, is a pin, *p*, which is held by one end of the rocking-arm, *k*, the other end of which is pivoted by a stud, *o*, around which

THE RAILROAD SIGNALS NOW USED.

[From the Eleventh Annual Report of the Massachusetts Railroad Commissioners.]

May 1880

RESOLVE IN RELATION TO THE USE OF SIGNALS ON RAILROADS.

Resolved, That the Board of Railroad Commissioners be instructed to investigate the subject of railroad signals, and to report the result of their investigation to the several railroad corporations in this Commonwealth, and to the next General Court. (Resolves, 1879, chap. 24.)

In conformity with this resolve, the Board gave extensive notice of public hearings, and have examined many models, and a greater number of working signals, on the railroads of this and other States. The great importance of the subject, and the attention given to it by railroad managers, together with its relation to other matters now under consideration, have induced the board to place their views, in the body of the report.

BLOCK AND INTERLOCKING SYSTEM.

There can be no doubt that, for security from rear collisions, and from accidents occurring by reason of misplaced switches or open draw-bridges, the block system carried out by interlocking switches and signals comes nearer to insuring immunity from accident than any other known device. The block system, long used in England, and now brought almost to perfection by interlocking devices, is so called because under it each section of road is "blocked" by signals against the entrance of a train while that section is occupied by another train. Improving on the former system, which only provided for an interval of time between successive trains, the block system secured an interval of space. Under it a railroad was divided into telegraphic sections. Before a train could start from the first station, a signal was sent from the first to the second, and a favorable reply was received; then a signal was made for the train to leave station one, and at the same time station two was notified of the fact; this notification was acknowledged, and the section was "blocked" by a signal showing that it was occupied. When the train reached station two, a signal was sent to station one that the line was clear, and the "block" was taken off. Of course, if the train met with an accident, or if it was delayed in reaching the second station, the section continued to be blocked, and no other train entered it until a signal from the second station gave notice that the danger had ceased. And the same precautions guarded every section throughout the line.

THE INTERLOCKING OF SWITCHES AND SIGNALS,

combined with the block system, not only secures each section from the entrance of a train while it is already occupied, but also blocks the section for any train while the track is broken by the throwing of a switch, or by the opening of a draw-bridge, thus removing these causes of numerous disasters, while it allows a vast increase in the number of trains.

The method, in brief, is by the use of levers, operating switches and signals, so interlocked that a signal of safety cannot be given while danger exists, and a danger cannot exist until after it has been signaled. In other words, the operator cannot, by negligence or forgetfulness, or even from malice, create a danger or suffer it to exist until he has signaled it afar off to any approaching train. He cannot open a switch before setting a signal at danger; having opened a switch, he cannot leave a signal at safety; he cannot set the signal at safety before closing the switch; he cannot leave the switch half closed without giving a signal of danger. All these four errors, each of which has cost many lives, are made impossible in a section of road guarded by this system. And the boast is not extravagant that, for this purpose, the working of signals is not trusted to the intelligence or to the fidelity of a man, but that each man becomes part of an unerring machine in which his will ceases to operate, and he must act in accordance with the principles of its mechanism.

Mr. Barry, in his work on railway appliances, gives a strong illustration of the perfection to which mechanical provisions for safety have been carried. At Cannon street station in London 70 switch and signal levers are placed in one signal house; making millions of combinations possible, if they were not interlocked. Of these combinations only 808 are safe. Yet a stranger blindfolded or blind, handling these levers at random, cannot produce a condition of danger. He could stop trains and hinder business, but he could not create a possibility of danger without signaling it in advance.

More than this—because the pulling of the wrong levers, although not causing immediate accidents, does strain the machine and thus might lead to the unlocking of the levers, with consequent disaster; therefore, the attempt and bare idea of pulling the wrong lever is checked by mechanical means, and the uncertain will of man is subordinated to the perfect mechanism of this device.

where a few of these signals are used, frequent breaking of the wires is complained of as giving needless signals of danger. The Fitchburg Railroad Company has had the signal on five miles of its road for more than a year, including the whole of last winter. Since May it has been in charge of the officials of the road, and their report is highly favorable. If it works well through the winter, it will have had that full and continued testing which such inventions need before they can be commended with entire confidence.

ROUSSEAU'S SAFETY RAILWAY SIGNAL.

This signal has already been referred to as used in blocking the New York Central and Hudson River, where it has been in successful operation for nearly four years. It resembles Hall's system in many points—among others, in using an open circuit. It resembles the Union electric signal in using gravitation as the power which actually gives the signals, thus requiring a less powerful battery than the devices where electricity does the direct work. The signal is set by a clock weight, and when wound up it signals 350 trains before it needs winding again. By an ingenious device the lamp on these signals cannot be removed for trimming without winding up the weight.

As in the inventions described before, the engine, when it enters a section, sets the signal at red, meaning danger, and it so continues till the train has passed off, when it sets it at clear, meaning safety. Each of these effects is produced by a "commutator," over which the wheels pass. In places of extra-hazard, two danger signals are used—one, called a distance or cautionary signal, 1,000 feet in advance of the signal within the section that is to be entered. If this distance signal shows green (or any color selected for the purpose) it indicates that the second signal is red; and the engineer must stop before entering on that blocked section. This system also provides each station-master with the means of stopping any approaching train, if danger has been shown to exist; and an indicator keeps him acquainted with every movement on his section of the road. An extra signal, to be used in foggy weather or in dark tunnels, is a rod which not only strikes the engine, but, by an additional device, causes the whistle to sound; and, it is said, it can be applied to the brake and made to stop the train. The long use of this signal in the Harlem tunnel is relied on as proof of its excellence. The application of the system to switches and draw-bridges needs no explanation; and the application of all these systems to a single track, while it presents points of difficulty, is a matter of detail which need not be discussed.

BEAN'S ATMOSPHERIC SIGNAL

is a safeguard against the dangers arising from open switches and draw-bridges; and it is also applicable to stations and crossings. A brief account of this device is given in Appendix G. The Old Colony road has tested this device by using it at exposed points for more than two years, gradually increasing the number of instruments in use, and now having them working at distances varying from 1,000 to 1,400 feet at one draw-bridge, two stations, and four switches. This signal is simple and inexpensive; and, so far as it has been used, and for what it undertakes to accomplish, it seems to be an almost faultless device.

In the appendix also may be found tables showing some results of the working of Hall's and of the Union electric signals; also brief accounts of devices which were exhibited to the board, but which are not subjects for full reports, because they have not been put to the practical test which is needed before such report can be made.

In conclusion, it is evident that the time has not come when the adoption of any one of the devices exhibited for giving automatic signals should be required by law. No party has asked for legislation; and Mr. Hall strongly disclaims any desire for legislative action. Nor, pending further experience on the part of railroad men, and further experiments by electricians and other inventors, can it be thought strange that railroad companies hesitate to equip their roads fully with imperfect devices, which may soon be set aside for better. Many ingenious men are giving their thoughts to railroad signals. The laws of the force, which most of them are trying to use, are not fully known, and the force is not capable of entire control. The railroad managers of England, and indeed of Europe, are more than skeptical as to the use of automatic signals, electric or otherwise. They would regard reliance upon such signals as criminal recklessness, if they were not supplemented by other appliances. Many railroad men in this country share this feeling; and this refers not only to railroad managers, who might be suspected of being influenced by undue economy, but to skilled superintendents and other experts who have no such motive. At present, no one has the right to say of any system of signals, as a whole: "This is the system that ought to be adopted on all roads." The desire is natural that some tribunal should decide at once which is the best, and that the Legislature should order its adoption. But the time for such a decision has not yet come, even if any automatic device can ever be found which will alone answer all the purposes of a safety railroad signal.

Yet it should be remembered that these imperfect devices do render great service in announcing danger and preventing accidents. The worth of a safety signal is to be estimated chiefly, not by counting the number of its false alarms, but by its well-founded alarms. Even an occasional failure to give warnings of danger, while it forbids sole and implicit reliance upon an automatic signal, does not prevent its being of great value as an auxiliary. When the terrible consequences of a railroad disaster are considered, a preventable accident becomes a crime. The public have a right to expect that their safety will be guarded by every reasonable precaution, and that devices designed for this end should not be rejected simply because they have not attained perfection. Railroad managers should be quick to guard their tracks, and especially all draw-bridges and other points of special danger, by those appliances that seem to them best adapted to insure safety. It is proper to add that our chief railroad companies have shown a praiseworthy spirit, both in testing new inventions and in adopting those that, upon trial, have commended themselves to their judgment.

The Metropolitan, September 24th 1881.

Electric Fire Alarms.—Several kinds of fire alarms are on view at the Paris Electrical Exhibition. In the simplest form, the person who gives the warning makes an electric contact between two wires, and this causes an electric current to go to the station and to ring a bell there. According to this system, there must be a separate bell and wire for each signalling station. There is another kind, in which one wire serves for a large number of different signalling stations, and at the central office a bell is rung and an index points to the particular station which has made the signal. The simplest form of this kind of instrument seen is the street fire alarm of Mr. E. B. Bright, which is entirely free from all clockwork or other mechanical movements, which are always liable to get out of order. In front of his exhibit and at the sides he has eight street posts such as are actually employed by the Metropolitan Board of Works. When a fire breaks out in any district the glass of the nearest alarm post—say, No. 4—is broken and a handle is pulled out. This immediately causes a bell to ring at the fire station, and the fireman turns a pointer round a dial until the bell ceases to ring. This will happen when the pointer is at No. 4 on the dial. He then knows the locality of the fire, and signals to the station that attention is being paid. The manner of doing this is extremely simple. A current is always passing through the wire which connects the different stations. It also passes through the circuit which rings the bell. Another current also passes through another circuit in the electrical bell, with a resistance inserted just sufficient to prevent the bell from ringing. When an alarm is made an additional resistance is added to the circuit, which disturbs the balance, and the bell rings until, by turning round the pointer on the dial, sufficient resistance has been put in to restore equilibrium. The number then indicates the particular station, as each station has a different resistance. Mr. Spagnoletti also has a simple form of alarm—the dial at the fire station has a pointer, which is moved round by a succession of electric contacts, like a Wheatstone's step-by-step alphabetic telegraph. The number of currents determines the position on the dial at which the hand will point. Each wall or pillar post in the streets has a box with a handle outside; when the handle is lifted a metal ball runs down inclined planes, making contact as it runs, and so sets the dial at the engine-house to the particular street whence the signal came. Captain Shaw, who recently visited the Exhibition, was particularly interested in a new signalling apparatus, capable of doing more than those just mentioned. This is the invention of Mr. Mackenzie, of America. It has only just been finished in time for the Exhibition here. Each station can send any one of ten messages, which may be "fire," "police," and so on. There may be 100 such stations on one circuit. The sender of the message presses down a lever and one of ten buttons, corresponding to the ten messages he can send. At the receiving station three wheels are set in rotation by gravity, and stop at the right place so as to show through three shutters the number of the station which is signalling and the object of doing so. The wheels are stopped by ratchets, and the position at which they are stopped depends upon the depth to which the ratchet has descended under the influence of a succession of currents coming from the signalling station. When the first of these revolving wheels is stopped its momentum releases a catch which brings the next ratchet and wheel into action, and then it in turn puts into gear the third. The mechanism is extremely simple—the transmitter consists of a clock train which moves a piece of metal over a series of contacts. The number of these determines the position at which the ratchet at the fire station will stop. The revolving wheel at that station is immediately caught, and sets the next wheel in rotation by the time the signals are ready to act upon it. This is an extremely interesting piece of apparatus. Its applications are not limited to fire alarms or police calls, and it requires a very slight addition to its bulk, and no additional complexity, to enable it to transmit ten thousand or even a million different signals from a single station.

LES POMPIERS et les COMMUNICATIONS TÉLÉGRAPHIQUES

La Science pour tous — Sept. 11th 1880

L'optimisme, en toute chose, est une disposition fâcheuse de l'esprit qui est souvent funeste au progrès, et ne permet pas de se tenir suffisamment au courant d'améliorations réalisées par autrui et dont on pourrait faire son profit; mais, en France, combien ne voyons-nous pas de gens qui pèchent par excès contraire et qui n'apprécient que ce qui se fait en dehors de leur propre pays!

Combien de fois n'avons-nous pas vu porter aux nues l'organisation des services destinés à combattre les incendies en Angleterre et en Amérique, par exemple, et affirmer que notre service à Paris est dans l'enfance! On nous a dit combien il fallait de minutes et de secondes pour atteler une pompe et la mettre en état de se rendre avec son personnel sur le théâtre de l'incendie; cela est fort bien assurément et nous serons les premiers à reconnaître l'excellence de cette organisation; mais, dans la pratique et dans les résultats, croit-on que nous soyons aussi complètement en retard que des esprits prévenus l'affirment?

L'expérience et la statistique démontrent que les pertes provenant du fait d'incendie sont sensiblement les mêmes à Londres, à New-York et à Paris, proportionnellement à l'importance de ces villes.

Le journal *la Lumière électrique*, dans un travail dû à M. du Moncel, notre éminent électricien, fait connaître que Paris possède un réseau télégraphique qui ne le cède en rien à ceux des villes étrangères qui ont adopté ce système.

On va pouvoir en juger.

A Paris, le corps des pompiers fait partie de l'armée et forme un régiment d'élite, composé d'hommes adroits, intelligents et dévoués. Ces hommes sont casernés et les casernes, au nombre de onze, sont réparties dans les différents quartiers de la ville. En dehors de ces casernes, et distribués à peu près également sur toute l'étendue de la capitale, existent plus de quatre-vingts postes qui sont reliés par groupes avec les différentes casernes, pourvues des engins nécessaires et ont toujours un nombre d'hommes suffisant pour parer à toutes les éventualités.

Enfin, il y a un poste central dans lequel est installé l'état-major, où arrivent tous les avertissements et d'où émanent tous les ordres. Ce poste central est relié télégraphiquement avec toutes les casernes.

Cette organisation, à laquelle on travaillait depuis plusieurs années et qui a fourni d'excellents résultats, a été terminée en décembre 1879. Ajoutons qu'une communication existe également avec la Préfecture de police, le Bureau central des Eaux, l'Assistance publique, l'Administration centrale des Télégraphes et enfin un certain nombre de dépôts de la Compagnie des Omnibus, pour obtenir, le cas échéant, des chevaux.

Les circuits qui réunissent tous ces postes fournissent une longueur totale de plus de 235 kilomètres de fils, qui sont presque entièrement souterrains et fixés à la voûte des égouts; 2.550 mètres seulement sont aériens. Par le fait, ce système est devenu toute une organisation de télégraphie qui a acquis une activité assez grande pour occuper journellement, au poste central, trois hommes et fournir des échanges de correspondances s'élevant en moyenne à une centaine de dépêches reçues et transmises chaque jour, soit pour signaler des incendies, soit pour des détails administratifs, soit pour des ordres de service qui en forment le plus grand nombre.

Il faut bien le reconnaître, les pompes à vapeur du service de la Ville de Paris ne sont pas aujourd'hui très-nombreuses, mais on en augmentera la quantité, et il est probable que, dans un court délai, on aura aussi des attelages tout préparés pour n'avoir pas besoin de s'adresser à des compagnies particulières; c'est là le seul point d'infériorité qui nous distingue encore de certaines grandes villes étrangères, comme Londres et New-York, bien que l'on n'ait pas encore eu à signaler d'une façon sérieuse l'insuffisance de notre matériel de secours en usage.

L'organisation télégraphique du Musée du Louvre pour les incendies présente des dispositions particulières que l'on ne trouve pas ailleurs, en raison des trésors artistiques dont la valeur est incalculable que renferme cet établissement. On a dû naturellement multiplier les appareils avertisseurs et indépendamment d'un certain nombre de sonnettes d'alarme, le gardien chef, le plombier et plusieurs autres agents sont en communication avec la caserne de la rue Jean-Jacques-Rousseau.

M. du Moncel, bon juge en la matière, estime que le système télégraphique des pompiers de la Ville de Paris *remplit toutes les conditions de sécurité désirables*. On ne s'en préoccupe pas moins vivement des améliorations à introduire dans l'organisation de ce service, et nous croyons savoir qu'on se propose de compléter le réseau télégraphique, déjà si important, par l'établissement d'un réseau spécial d'avertisseurs électriques disséminés sur tous les points de la ville et mis à la disposition du public.

Nous croyons en avoir assez dit pour permettre de reconnaître que notre capitale n'est pas aussi déshéritée que l'on voudrait bien le dire au point de vue spécial qui nous occupe.

Ce n'est pas seulement à Paris que la question est à l'ordre du jour; nous savons que déjà, dans plusieurs villes de province, notamment à Reims, la télégraphie électrique a été utilisée pour le service de secours en cas d'incendie. Il y a encore beaucoup à faire, il est vrai, mais ces améliorations ne sauraient tarder à être apportées dans un service dont tout le monde reconnaît l'importance au point de vue de l'intérêt général et particulier.

Engineering

1212. Electrical Fire Alarms: C. E. Spagnoletti, London. (6d. 4 *Figs.*)—The apparatus has a train of clockwork to run off paper ribbon (similar to a Morse instrument); it is started into action by the current that gives the signal from the place of alarm. A bell and an indicator denote when the instrument requires re-winding. Alarm bells call attention to a signal. These bells may be of the ordinary "trembling" system, but attached to them is an earth connexion for the bell hammer to work so that the line wire may be discharged and any number of bells connected with one wire. A code of letters or ciphers is used to denote the station from whence the alarm came. In the figure the improvements are shown adapted to an ordinary instrument. The wheel *a* has on it slots *b* and projections of metal (not shown) for producing a rubbing contact with the spring *c*. The wheel is rotated by the instrument, and the contact with the spring *c* makes the

31

required letters or ciphers; *d* are coils which set the instrument in motion, when the armature *e* is brought in contact, *f* is the pointer, *g* the quadrant for indicating when the instrument requires winding. Refers to two other arrangements for signals and makes three claims: (1) Connecting the bells to the earth for discharging the line wire. (2) An arrangement of graduated slopes in connexion with a bell for sending signals. (3) The automatic system for starting the receiving instrument. (March 20, 1880).

35

and then to make its elongation and contraction by low sounds evident to the eye.

It therefore appears from these experiments, that wires conveying those currents of electricity which are required for telephonic purposes expand and contract as they are heated and cooled, and as the variations in the strength of the current are small compared with the strength of the current itself, the expansion and contraction vary in the same ratio as the condensation and rarefaction of the air particles conveying the sonorous vibrations which produced these vibrations.

The mechanical changes, or molecular vibrations in the wire, due directly or indirectly to telephonic currents, which result in the reproduction of sound, bear a close analogy to the mechanical changes due to the direct transmission of sound, but with this important difference, that while the vibrations due to sound are progressive along the wire, and their velocity is low and easily measured, those due to thermal effects are practically instantaneous, and therefore affect simultaneously the whole length of the wire.

Note.—De la Rive, in 1843 (*vide* "Electricity," vol. i., p. 304), observed that an iron wire emitted sounds when rapid discontinuous currents were passed through it, but he attributed the effect to magnetism, for he failed to obtain the same effect in non-magnetic wires like platinum or silver.

Graham Bell found, in 1874, that a simple helix without an iron core emitted sounds, and (in 1876) that very distinct sounds proceed from straight pieces of iron, steel, retort carbon, and plumbago when conveying currents.

Professor Hughes showed that his microphone was reversible, that is, that it could receive as well as transmit sonorous vibrations.

Mr. Weisendanger (*Telegraphic Journal*, Oct. 1, 1878) reproduced sounds on a microphonic receiver, which he called a thermophone, and attributed the effect to its true cause, viz., the expansion of bodies under the influence of heat, which, in fact, is the explanation of all microphone receivers.

Ader reproduced speech by the vibrations of a wire conveying currents of electricity, but he found that only magnetic metals were effective, and therefore, like De la Rive, he attributed the result to magnetic agencies. (*Vide* Count du Moncel, *Telegraphic Journal*, March 1, 1879.)

These and many other sonorous effects of currents on wires may be really due to such heat effects as I have described.

W. R. SYKES' DOUBLE ARM BLOCK INSTRUMENT.

As used on the Main Line of the London, Chatham and Dover Railway.

Fig. 4 is a front view of a complete instrument for working both the up and down traffic, and is fixed at each end of a section. A (fig. 4) is a dial fitted with two arms, B and O.I., mounted behind a post, C; the arm, B.I., on the right hand side of C is worked by an insulated rod, D (figs. 1, 2, 3), connected to the reversing axle, E (figs. 1, 2, 3), the end of which passes to the outside of the case, and by means of knob F (figs. 1, 3, 4), can be turned to the right or left. On the other end of reversing axle, E, is fitted a cam, G (fig. 2), which works between two springs, H, H.I. (figs. 1, 2, 3).

The double stud, I, I.I. (figs. 1, 2, 3), is fixed between the springs, H, H.I., on the back of case, and on turning the knob, F, say to the right, the reversing axle, E, with the cam, G, turns also, cam G taking spring H.I. away from the pin of stud 1, and allowing spring H to make contact with the pin of stud I. Cam G also makes contact with H.I.

Spring H is connected to the zinc of the battery; spring H.I. to the copper of the battery.

The turning of knob F, in addition to reversing the battery connections, also (by means of rod D) moves the arm, B.I., to a horizontal or "danger" position. By depressing the key or tapper, K (figs. 1, 2, 3, 4), which is connected to terminal 4 or Line, the latter, by means of the contact block, M (figs. 1, 2), is connected to reversing axle E and cam G, and thence to spring H.I. By the depression of the key also, the insulated back portion, *k*, of the key or tapper, K, raises a spring, N, which, together with terminal 6, is connected to terminal 1 or Earth, into contact with stud I, I (stud I being in contact with spring H), thereby sending the Copper current to Line and the Zinc to Earth.

By turning the knob F to the left, the arm, B.I., is lowered to "Clear," and the key being again depressed, the current is reversed, Zinc going to Line, and Copper to Earth.

The foregoing describes the arrangement for sending reverse currents, which is all mechanical. We will next consider the working of arm B, which is controlled by the instrument in the next section. Arm B is mounted on an axle having behind the dial a steel arm, O (fig. 2), kept magnetised by magnet P (figs. 1, 2, 3), working between two shoes, *n*, *s*, of the electro-magnet, Q (figs. 1, 2, 3). In giving "train on," by depressing key K, without moving knob F, arm B being at "clear," a current is sent to the electro-magnet of the instrument in the next section, which rings the bell there by attracting armature R (fig. 3), but does not alter position of arm B of that instrument. If the train is accepted, the knob, F (of instrument in next section), will be turned to the right, putting arm up to "danger," and the key depressed sending a current to line (which enters *viâ* 4, K, M.I. (fig. 2), to terminal 5 (fig. 2) into electro-magnet Q; from thence it passes through terminal 6 (fig. 2) to earth. This causes arm O to be moved from *n* to *s* (fig. 2), raising arm B to "danger."

When a "clear" signal is given, knob F will be turned to the left and arm lowered to "clear," the key depressed, and a reverse current sent into electro-magnet Q, which will bring arm B to "clear." It will be seen that the current passes direct from the battery without going through any coils or electro-magnets to line, thus saving a great portion of the ordinary gear put into block instruments.

In whatever position the arm of one instrument stands—Up or Down, Clear or Blocked—so the current is sent, putting the corresponding arm at the other end of the same position.

These instruments have been made partly from the old tapper bells by "Izant," and make a good and cheap block instrument with only *one* wire. The cost of each instrument is about £5 10s., and the old tapper bells can be altered at much less cost.

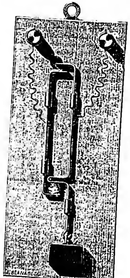
APPAREIL ÉLECTRIQUE AVERTISSEUR

DES INCENDIES

On a déjà imaginé un certain nombre d'appareils qui ont pour but de faire entendre une sonnerie électrique d'alarme, dès que la température du milieu où ils sont placés s'élève au-dessus de la moyenne normale. On connaît l'avertisseur, qui consiste en un simple tube thermométrique à mercure; quand le mercure s'élève au-dessus d'un certain niveau par suite d'une élévation de température anormale, il arrive à toucher deux fils de platine séparés l'un de l'autre et mis en relation avec une pile électrique et une sonnerie; en les touchant, il ferme le circuit et la sonnerie fonctionne.

M. G. Dupré vient de faire construire chez M. Dubosq un appareil basé sur le même principe, mais dont la disposition est nouvelle et originale.

Deux tiges métalliques AB, CD sont mises en re-



Appareil électrique avertisseur des incendies.

lation avec la pile et la sonnerie électrique par l'intermédiaire des boutons P et Q. La tige CD est séparée de la première tige AB, qui est fixe, par une petite masse de suif placée à la partie inférieure, des deux tiges (voir la figure ci-dessus). Si la température vient à s'élever par suite d'un incendie, le suif entre en fusion, la tige CD, sollicitée par le poids K, s'abaisse et arrive en contact avec la tige AB; le contact s'établit, comme on le voit ci-dessus, à la partie supérieure du système. Le circuit est alors fermé; la sonnerie d'alarme se fait entendre.

ALARM SIGNALS FOR STEAM-BOILERS.

ARRANGEMENTS for signalling when the pressure in a steam-boiler rises above a certain point, or when the water falls below a certain level, have been recently patented by Mr. W. White, of Greenock. The patentee employs an electric bell, which may be placed in the office, or in some place where attention will inevitably be called to the neglect of the boiler attendant. In the arrangement, as applied to the pressure-gauge of the steam-boiler, in addition to the usual indicating hand or pointer, moving round the dial face of the gauge, and marking the pressure of the steam in the boiler, there is fitted a stationary pointer, which may be moved round by hand, and set at a point indicating any desired degree of pressure, on a swivelling pivot, centre pin, or stud, fitted in an eye in a small metallic bracket or rod, secured over the face of the gauge to the metallic case, or bezel ring, holding the usual glass face, but separated or insulated from that case or ring by a wooden, vulcanite, or other non-conducting piece, interposed between the metallic portion of the bracket, or rod, and the ring or case. This fixed or stationary hand or pointer is fitted with a tip of platinum soldered on, or provided with an inner projecting pin or stud, with which the moving indicating hand or pointer, or a curved platinum wire thereon, comes into metallic contact, when by the boiler pressure it is caused to travel round the gauge, to indicate the pressure at which the stationary hand is set. The insulated setting hand or pointer is connected by an insulated wire or rod, passing out of the gauge through the insulator, with a wire held by a binding-screw in contact with the gauge, and leading to one pole or electrode of an electric battery, and the usual moving hand or pointer is also connected by a wire attached to the case, and leading from the gauge through the magnet coil of an ordinary electric trembling bell to the other pole or electrode of the battery. When the pressure of the steam in the boiler causes the moving hand to travel round to, and make contact with, the projecting pin or platinum tip, on the setting pointer or hand, the electric circuit is completed through the wires and the pointers of the gauge, and causes the bell to ring and warn the fireman or attendant, until the pressure of steam is again reduced. The bezel ring holding the glass over the face of the gauge, is hinged, or it may be otherwise fitted to it, and securely locked by means of a padlock fitted after the stationary hand or pointer is set at the number expressing the limit or pressure to which it is desirable or safe to work the boiler, so that this hand may not be reset or tampered with by the fireman or other attendant. In cases where the maximum of pressure to which the boiler is worked would be constant, or never exceed a given amount, an insulated terminal plate might be fitted to the metallic bezel ring of the gauge, with which the moving hand or pointer would come in contact when it reached to, and indicated, the limiting pressure, and would then cause the electric bell to ring, or give an alarm. The apparatus may also be made to sound an alarm when the boiler pressure, as indicated by the gauge, becomes lower than is desirable, by fitting an additional insulated hand, which would be set at the minimum working pressure by hand after steam is raised in the boiler, and the moving hand indicates a higher pressure. The same arrangement of apparatus is obviously applicable to vacuum gauges. In the application of the improved apparatus, which is intended to give an alarm or warning of the water in a boiler either rising considerably above, or falling below, the normal position, the usual rod or lever passing from an indicating float in the boiler is fitted with small pointers or levers, and is connected by metallic contact of the parts of the boiler to a wire attached to the boiler, and leading to an electric battery. When the float rises or falls with the water in the boiler, considerably above or below its usual level, these pointers correspondingly rise or fall, and come into metallic contact with a platinum contact point on a stationary insulated terminal plate, connected by a wire leading through the magnet coil of a trembling bell to the battery, and causes the bell to sound an alarm to indicate such unusual rise or fall of the water-level. By a slight modification of this alarm apparatus, the float is connected by a cord or chain with a balance-weight passed over a pulley carried on a spindle in a bracket over the boiler. The spindle of the pulley is fitted with a hand or pointer, which moves with the pulley as it oscillates or revolves by the action of the float and weighted cord; and when this pointer moves considerably round to one side or other to indicate in the usual manner an extreme rise or fall of the water in the boiler, comes into metallic contact with a stationary pin or stud of platinum or other metal on either side of the usual indicating segment, which is in this case, however, insulated from the bracket. The insulated segment and bracket are fitted with wires, leading to a battery and bell coil, and the making of contact between the pointer and stud causes an alarm to be sounded, and indicates audibly that the water level is extremely high or low. In these arrangements of safety alarm signalling apparatus described, the electric bell might be fitted in the engine-room, and an additional electric bell, acted on by the same battery, and set of wires, might also be placed in the manager's or engineer's room. In works where a large number of boilers are used, the improved apparatus can be connected to the gauges or water-level indicators of each boiler, and only a single bell used in the engine-room or manager's office.

Another arrangement for indicating low-water, which is not patented, we believe, is the electric indicator of MM. Lethuillier and Pinel, of Rouen. By means of this apparatus, the water-level in a boiler may be ascertained at any distance from the latter. The arrangement employed for this purpose consists of an indicating tablet, which may be placed in any part of the establishment, however remote from the boiler-house, in the office of the engineer, or the superintendent, or within reach of the boiler inspector. This tablet is connected with the electric indicator, which is fixed at the top of a vertical tube above the boiler, by two electric conducting wires. At the lower part of the scale of the indicator are placed two pieces of copper, upon each of which is fastened a small plate. These platinum wires are superposed at a distance of 0·08in. When the index, which is attached to a vertical rod connected to the float in the boiler, descends, it rests on the upper plate of platinum, depresses it, and puts it in contact with the lower plate. An electric current is thereby established from a battery, connected with the apparatus, causing a bell on the indicator to ring, while, at the same time, the sign "low water" appears on the tablet. Similar pieces of copper and platinum are fixed at the upper part of the scale, and when the index reaches this limit in consequence of the rising of the float, the bell rings as before, and the indication "high water" is shown on the tablet. In order to remove the warning word from the tablet, a button is pressed, which returns the indicating parts to their normal position.

Engineering News

Mr. W. J. Phillips, superintendent of the police and fire alarm telegraph, of Philadelphia, says that the present system is twenty-five years old, and the majority of the lines are almost worthless, needing constant repairing and great battery power to keep them up to their work; that they might be patched up and even extended, but their usefulness would be shortlived and the expenditure of money for that purpose injudicious. In one section, comprising the First, Second, Third, Fourth, Fifth, Seventh, Eighth, Ninth, Twenty-sixth and Thirtieth wards, there are forty-four boxes, but there should be seventy in addition, or one hundred and fourteen in all. In another section seventy-five more boxes are needed. Mr. Phillips estimates the total cost of improving and extending the system at \$81,300, of which amount \$45,300 is required for new boxes and repairs, \$24,000 for work and material, and \$12,000 for refitting the Central Station.

REPRODUCTION DES SONS

SOUS L'INFLUENCE DE LA LUMIÈRE

PHOTOPHONE DE M. GRAHAM BELL

—

B1

Il nous est arrivé tout dernièrement d'Amérique la relation d'une communication très-intéressante que vient de faire M. Graham Bell à la dernière session de l'Association américaine pour l'avancement des sciences, sur la production des sons par l'action de la lumière, phénomène qui l'a conduit à un nouvel instrument auquel il a donné le nom de *photophone* (1).

Au moyen de cet appareil, un rayon lumineux projeté à distance sur une substance impressionnable à la lumière, peut, étant modifié dans son intensité sous l'influence des vibrations de la voix, impressionner suffisamment cette substance pour que celle-ci puisse reproduire la parole avec l'aide d'un téléphone, *même sans téléphone*, sous certaines conditions. De cette manière on peut parler à travers l'espace *sans fils conducteurs* et aussi loin que le rayon lumineux peut agir sur la substance sensible. Est-ce là cette invention qu'on nous a fait entrevoir comme ayant été l'occasion du pli cacheté déposé par M. Bell à l'Institut de Franklin, ou une invention collatérale?... Si c'est la première hypothèse qui est la vraie, j'avoue que tout ce qu'il y avait de mystérieux dans cette découverte, pourrait se réduire à la proportion d'un fait ordinaire; car la découverte actuelle, bien que très-intéressante, n'a rien par elle-même que de très-compréhensible, puisque depuis longtemps on sait que la lumière détermine sur les substances photogéniques, des actions physiques ou chimiques qui peuvent intervenir, comme l'a démontré M. Ed. Becquerel, soit pour déterminer des actions électriques, soit pour modifier l'intensité des courants transmis par leur intermédiaire. On a, d'ailleurs, démontré que le téléphone permet de révéler la présence de ces courants quand ils sont interrompus et quelque faibles qu'ils soient; toutefois la production des sons par *l'action directe* de la lumière est plus extraordinaire, et montre une fois de plus combien nous avions raison de dire, que des *vibrations sonores* peuvent *parfaitement résulter d'actions moléculaires*. Cette fois on ne viendra plus nous parler de la *nécessité de vibrations transversales*, et MM. les acousticiens seront bien obligés de reconnaître que leur science est bien peu avancée.

Ce qui est surtout curieux dans les expériences de M. G. Bell, c'est que la propriété d'influencer moléculairement les corps de manière à changer certaines de leurs propriétés physiques, n'est pas le propre du sélénium ni des substances photographiques; ce serait, suivant lui, une *propriété générale*

(1) Il paraît que cette idée était déjà venue à Bell dès 1878, et que, dans un mémoire présenté par lui à la Société royale de Londres le 17 mai 1878, il a dit qu'il était possible d'entendre l'effet d'un nombre interrompant l'action de la lumière sur une plaque de sélénium. Déjà en septembre 1878, dans la première édition de mon ouvrage sur le téléphone, p. 193, j'avais indiqué des expériences de MM. Willoughby-Smith et Siemens qui montraient qu'on pouvait obtenir des sons, en projetant un rayon lumineux sur une goutte de sélénium introduite entre deux électrodes de platine dont les dents étaient intercalées dans leurs intervalles respectifs, et mises en communication avec un téléphone à pile.

THE FIRE TELEGRAPH OF PRAGUE AND SMICHOV.

Engineering Oct 8. 1880

(Concluded from page 226.)

We shall now describe the arrangement of the street boxes by reference to our illustrations Figs. 2, 3, and 4, annexed. The annunciator shown in these figures resembles in its chief features the instruments made by Messrs. Siemens Brothers, and which were described in these pages some time ago.* The present instrument differs, however, from Siemens' apparatus in some interesting particulars. The chief part of the apparatus is a train of clockwork driven by the weight F. This clockwork when moving turns a contact wheel A, the circumference of which has a series of suitable projections. By these projections the spring B is raised from the contact C on which it rests during the intervals. In the position shown in Fig. 2, the (constant) current is freely passing through C and B. If a signal has to be given, the handle D is pulled, when the clockwork is released, and the wheel A begins to revolve. Whenever a projection of this wheel passes below the lever B, the current is broken, and as each breaking of the current causes a dot or dash (according to its duration) to be made by the Morse apparatus at the central station, it is easily understood, that according to the shape of the wheel A various signals will be given by different instruments. Every instrument has a wheel of a shape differing from all others. The apparatus shown in our engraving would, *e.g.*, send the signal . . —, (the letter *b*), which would be repeated thrice, as the wheel A makes three revolutions whenever it is released, after which it is automatically stopped.

In order to be ready for service, the apparatus must be wound up, which is done by the little handle E hung up for that purpose in the case of the instrument. As in Messrs. Siemens' apparatus, no ordinary sending key L is fixed in the case, so that any person practically acquainted with telegraphy can correspond with the central station. In the fire annunciator of Messrs. Siemens Brothers a galvanometer is included in the circuit. This galvanometer serves a double purpose—first, it does duty as a receiving instrument in corresponding with the central station;† secondly, it shows by its movements whenever the line is used by some other annunciator, preventing thus practically a double use of the same line. In the apparatus we are just describing, however, the galvanometer is replaced by a small relay K, whose armature carries a light arm striking a bell whenever the armature is released by a breakage of the current. This arrangement has some advantages. The movements of the needle of the galvanometer may easily pass unnoticed, especially at night, whereas the sound of the bell is at once more intelligible to the general public, and facilitates the "reading" of an answer by a trained telegraphist. In fact correspondence may be carried on in the dark, which is not possible when a galvanometer is used.

As a special feature of novelty, however, the arrangement of the electrical connexions within the instrument must be described. The apparatus is placed in a casing which is closed by a glass door. Whenever this door is closed it presses back a button G, which establishes a contact between two pieces H and I, as will be understood from Fig. 3. Thus, whenever the door is shut, the current will pass through the apparatus by the following way, viz., (Fig. 2) 1, H, I, 2, 3, 4, 5, 6, 7, 8, 9, 10, C, B, 11, 12, 13, 14, L, 15, 16, 17, 18, 19, 20, 21. If, however, the door is opened for the purpose of using the apparatus, the button G is released, and the contact between H and I is broken (as shown in Fig. 3). Now the current entering at 1 and passing to H cannot go directly to I, and it is therefore obliged to go by *a*, *b*, *c*, *d*, through the relay K, then by *i*, *m*, *n*, *o* to 2, from whence it takes the same course as described before. In other words, by opening the door the current is prevented from passing directly from H to I, and it is therefore obliged to take a circuitous route passing through the relay K. The advantage of this arrangement will be easily understood. The receiving apparatus, whether a galvanometer or relay, presents always a considerable resistance to the passage of the current. Now, if a large number of street boxes is included in a line, the aggregate resistance of all their receiving instruments is very great, and requires a battery of high power. In the apparatus as described, however, the current does not pass through the relay, unless the annunciator is used. Thus the ordinary resistance—when all relays are put out of circuit, all doors being shut—is very small, and even when a street box is used, only one relay is put in. As a matter of course a considerable saving in battery power is the result, an important item in a system worked by a constant current. This arrangement has been introduced by Mr. Francis Schmidt, of Prague.

Finally, it remains to explain the action of a circular brass disc M, shown at the bottom of the case in Fig. 2. Should the cord carrying the weight F break, or should the weight run down, the weight would fall upon the disc M, and, pressing it down, would establish a contact between two wires β and γ. Thus a new way (6, α, β, γ, δ, 13) is opened to the current and the line remains unbroken even if the wheel should happen to be just in such a position as to hold the arm B raised from the contact C.

The annunciator cases just described are enclosed in wooden boxes, which are fixed to the outside of the houses in such a way, that their face is flush with the wall and their lower edge is about 4 ft. to 4½ ft. above the ground. Externally these street boxes are painted grey, the middle field being red. This red field bears in white letters the designation "fire annunciator" in both current languages ("Pozarovy automat" and "Feuer automat"). In the centre of the field a small ornamental casting in white metal, representing the arms of Prague, is fixed. The number of the line (III.) and the designation of the annunciator (*b*) are also given.

These street boxes are locked, and can be opened only by means of a key. The locks are, however, of the simplest description, and they are made all of the same pattern, so that any box can be opened by any key. Every policeman, and every nightwatch, as well as the concierge of the house where the firebox is fixed, is provided with a key. The glass door of the inner casing is simply shut without being locked.

It is, of course, open to question, whether such a system of limited access to the fire-bells is preferable to the possibility of a free use. The number of false alarms would be certainly increased by a free access to the annunciators, at the same time the instruments would be more liable to be damaged; on the other hand, however, the chief advantage of a fire telegraph, the saving of time, is much reduced if the annunciators are accessible only by means of a key which is in the possession of persons who are not always on the spot just when

ELECTRICITY v. FIRE.

The first five minutes' work at extinguishing a fire is, it is said by competent authorities, worth all that can be done in the next five hours. Few will dispute this, and therefore the question of how we are to obtain hold of this precious five minutes is one well worth consideration. In America, besides all the wonderful arrangements for dropping the driver of a fire-engine through a trap-door and down an inclined plane into his seat, electricity has been largely employed to gain time, and in London the mere connexion of the fire stations with one another by telegraph has been for many years in use, but the mode of warning the fire stations in London has until recently been entirely dependent on messengers from the neighbourhood of the fire itself. Thus more than five minutes is always lost.

Mr. Edward Bright has attacked this precious five minutes by electricity in two different ways. The first, and what we may term the saving of the messenger's-time-plan, is the one that concerns the public generally the most. It consists in having posts in the street from which any policeman or authorised person having the key of the box in his neighbourhood can, by pressing a knob after opening the box, call the attention of the fire station to the fact that a fire has occurred near that particular box, and the second plan consists in arrangements by which fire in any large building gives its own warning, and by a little manipulation shows at once its particular locality in that building. The first system is one that should be employed therefore in every town, and the second in every building of special importance. Both depend on a very clever application of the principle of the Wheatstone bridge used in telegraph testing. Taking first the street arrangement: In the fire station we have an arrangement of the Wheatstone bridge in which the two fixed resistances of the bridge exist in the ordinary form, and in place of the galvanometer a relay which acts on a bell. The third part of the balance consists of coils of definite resistances which can be brought into circuit by moving a handle, and the fourth part consists of the lines of wire which join the various posts and of definite resistance coils varying at each post fixed at the posts themselves. Thus suppose No. 1 post has 10 units in its coil then No. 2 has 20 units and so on; these resistances are cut out of circuit at the boxes, and can only be placed in circuit by pressing the alarm knobs. When the arrangement is ready for use all these coils are out of circuit, and as the resistance of the line is balanced by suitable coils in the third side of the balance, the current, which is constantly kept on at the station, has no effect on the bell, since the relay circuit which rings the bell joins two points of equal potential. On pressing a knob the resistance at that post is thrown into circuit, the balance is disturbed, and a current passes through the bell relay ringing the bell.

The person in charge at the fire station having his attention thus called, proceeds to find the number of the post where the knob is pressed. This he does by turning on resistance coils in the third side of the bridge by means of a handle, until the bell ceases to ring, and the place where his handle stops indicates the station calling, as the resistance thrown in corresponds with the resistance added at the calling post. By suitable means he can also give a signal to the post calling to indicate that the call has been received. The system is in use in a part of the City and Borough, the posts being connected through one of the wires belonging to the Post Office. Already, between August 25 and October 11 of this year, twelve fires have been signalled to the Fire Brigade stations. In some of these cases the engines had actually arrived at the fire summoned by the alarm before the messengers had arrived at the Fire Brigade station. In the system actually in use the knobs when pressed place the resistances in circuit in which the current is constantly on. But Mr. Bright also adopts the plan of having all the resistance bobbins in circuit, and the knob merely making earth and thus cutting out all bobbins beyond that one. A third plan is evidently possible, which seems to us as preferable, and that is to have the end of the line insulated, and let the press of a knob place line to earth through the definite resistance of that particular post. No doubt by practice the best system will be discovered, but this adaptation of the Wheatstone bridge as a means of localising a fire call is decidedly ingenious, and a step in the right direction.

For the detection of fire in buildings and localising it the same principle of the Wheatstone bridge is employed, only the contact is made automatically by the action of increased temperature on a spring made of two metals. Thus in each room of a building to be protected is a small bobbin of wire offering a definite resistance. All these bobbins are in consecutive circuit, and connected in one of the sides of the Wheatstone bridge. Near each is a small box containing a spring, which when the temperature to which it is exposed rises to a certain point, makes a contact between that part of the series of bobbins and a wire leading direct to battery. Thus the electric balance is disturbed, the bell rings, and by turning a handle until the bell ceases to ring, the watchman can find the exact room where the rise of temperature occurs. There seems to be nothing in this arrangement open to objection, and when we consider the complicated clockwork arrangements used in America, Mr. Bright's seems simplicity itself, and one well worth a trial in our public buildings. When we recollect that during the last forty-five years the Houses of Parliament, the Royal Exchange, and a large part of the Tower of London have been burnt down, to say nothing of Covent Garden, Her Majesty's, and half a dozen other theatres, besides numerous large warehouses, mills, &c., it is certain that no system which offers such a fair chance of success in giving instant warning of fire should be allowed to be neglected whilst our public buildings run the risk, which they certainly now do, of being destroyed at any moment by fire for want of some means of giving notice within that first five minutes which the fire authorities hold in such reverence.

Electrician Dec. 11. 1880

LITERATURE.

Electrician Dec 11th 1880

Beschreibung der Neuen Feuertelegraphen-anlage in Stuttgart Von W. E. Fein.

In the whole history of the electric telegraph there is probably nothing more surprising than the slowness with which it has in this country, and on the Continent generally, indeed, been specially applied to the announcement of fires. Its application to this purpose seems to have been initiated by America, and there certainly carried to a high degree of perfection. This remissness is the more unaccountable as, apart from the obvious advantage, theoretically, of using such means, the logic of facts is overwhelming in favour of such a course.

Two years ago the municipal authorities of Stuttgart awoke to the desirability of having a system of fire telegraphs, and placed the work in the hands of a local firm of electrical instrument makers, Messrs. Fein, who have just published a clear and well-illustrated little book, describing how they carried out the undertaking.

The telegraph system at Stuttgart is worked on the radial—not the circle or loop line plan—that is to say, the Automatic Fire Annunciators, as they are called (we should have preferred indicator), the speaking Morse and telephone stations (Messrs. Fein having adopted telephones in some instances) all radiate from the central station, with which they are in circuit.

The Stuttgart automatic fire annunciators are worked upon the ordinary principle of a permanent current from the central office, broken by pulling the little knob, and thus allowing the contact wheel to rotate. The periphery of this wheel is so shaped that it breaks the current in such a way as to form, *ipso facto*, a certain letter of the Morse alphabet, which signal is produced, of course, on the instrument at the central station. This signal is varied in such a manner that each point has its own special one, and this indicates the position near which the fire has broken out. Instead of having the key of the automatic fire indicator kept by the police or at the house nearest to it, Messrs. Fein advocate the plan of lightly soldering it to the box itself, from which it can easily be broken off and used when necessary, by which means much invaluable time may be saved—the policeman, even in Germany, not being always at hand when wanted—which applies also to unofficial persons, who are likewise liable to mislay keys as well as other important things.

The Palace and Royal Theatre are included in the 75 points from which fires may be indicated, as well as the towers of 2 churches, the Stuttgart municipal authorities taking a very different view to that of a High Church vicar in a suburb of London, who a few years ago refused to allow the fire escape to be kept against the parish church, which he considered it would desecrate. By an ingenious arrangement of Messrs. Fein's the watchman at each church tower must make the circuit of the tower before he can give the signal to the central office, which is done every night at certain fixed times, showing that he is attending to his duty. In view of the enormous reduction of serious fires effected by the use of a good telegraph fire system—4 per cent. as against 29 per cent. formerly—it is to be hoped that in this country we shall more generally avail ourselves of such valuable aid in overcoming one of our most dangerous enemies to life and property.

31

FIRE-DAMP AND ELECTRICITY.

A most ingenious plan for detecting the presence of fire-damp in mines in time to obviate its disastrous effects has been recently suggested by the celebrated Belgian engineer, M. Somzee, whose eminent name and well known experience are sufficient guarantees that he would be the last man in the world to lend his name to anything chimerical. It is well known that the safety lamp is at present the sole indicator of the approach of fire-damp usually employed; and it is equally notorious that its warnings, in nine cases out of ten, come too late. The flame of the safety lamp elongates, and gives out a more intense heat whenever the fatal gas is at hand; but before those who are on the look-out for those infallible indications of danger can effect their escape, the proportion of fire-damp in the air has already become too strong for them, and the inevitable explosion overwhelms them in an instant. M. Somzee proposes to organize a series of indicators capable of giving instantaneous notice of the presence of fire-damp in any part of the mine, so as either to afford the miners time to escape, or enable the mining engineers to remove the danger by regulating the ventilation of the mine before the gas has had time to collect in dangerous quantities. For this purpose he utilizes the elongation of the flame of the safety lamp, and its increased caloric power (already alluded to) in the air infected by fire-damp, in the following way. A number of safety lamps, each provided with a specially prepared but very simple apparatus worked by electricity, and under the control of a mining engineer in a central office, are placed at different points of the mine, each lamp being connected with a bell at the central office by means of a metallic wire. The bells and lamps have corresponding numbers, and the sounding of one of the bells is the signal of an escape of fire-damp in that part of the mine where the lamp corresponding to it is placed. But this is not all. M. Somzee has discovered in the telephone a still more reliable agent for detecting the approach of the insidious fire-damp. The flame of the safety lamp, as it begins to dilate in its cylinder, should, if the cylinder be properly disposed, commence to sing, and if the upper surface of the lamp is provided with a telephonic apparatus in connection with a receiver at the central office, the receiver will begin to sing at the same time as the flame. Fanciful as this scheme may appear, it appears to have been received with great favor in Belgium, and no doubts seem to have arisen as to its practicability. The singing bird in the eastern fable, which warned the young prince of impending danger, will, if this scheme be carried through, be quite eclipsed by the singing telephone warning the miners of the near approach of their deadliest foe.—*Building World.*

M. Somzee, a Belgian engineer, proposes to utilise the safety lamp for revealing the presence of fire-damp in collieries. It is well known that the flame of the lamp elongates and gives a higher calorific power when in air which contains light carburetted hydrogen, or marsh-gas. A piece of metal is placed so as to be elongated by this flame; this produces electric contact, and causes a bell to ring. Several of these lamps should be placed in different parts of the mine, and the bells numbered.

OBITUARY.

ANSELL.—On the 21st December died George Frederick Ansell, who was well known to the scientific world by his fire-damp indicator, intending to prevent explosions in coal mines. Mr. Ansell was born in 1836. In early life he studied surgery, but not finding it suited to his taste, he decided to attend the lectures at the Royal College of Chemistry and the Royal School of Mines, where he was soon appointed lecture assistant to Dr. Hofmann. His next appointment was to the professorship of Chemistry at the Royal Panopticon, where he succeeded in volatilising gold, and made important experiments upon iron, steel, &c. In 1855 Lord Palmerston gave him an appointment in the Royal Mint under the mastership of Mr. Thomas Graham, where he rendered valuable services and obtained considerable credit by his treatment of brittle gold. His pen was usefully employed in numerous essays, his most important literary work being *The Royal Mint*.

HOW RAILWAY TIME IS KEPT.—There are in use between Albany and New York 18 electric clocks, two of the number being placed in the waiting-rooms, and one in the dispatcher's office at the Grand Central Depot, New York. The time on the clock in the depot at East Albany corresponds exactly with the time in New York. Each one of the clocks is connected with the general superintendent's office in New York, in which the railroad time is kept on what is called the "big clock." Conductors, train men, and others are compelled to keep their watches in strict conformity with the superintendent's clock. It is set by standard time, and connected with the time service department of the gold and stock telegraph. The time is distributed all over the line each week day as follows: At 10 o'clock 58 minutes and three seconds A.M. the word "time" is sent by the main office to the telegraph stations between New York and Albany. The word is repeated for 28 seconds, during which time operators must see that their instruments are adjusted. At 11 o'clock and 50 seconds, seconds commence beating, and continue for 30 seconds. The word "switch" is then sent over the wire, and operators having having electric clocks connect them immediately with the circuit known as No. 9 wire. Ten seconds are allowed in which to make the connection. At 11 A.M., with one touch of the New York key, the hands on the different clocks are set to 11 o'clock.

31

Electric Signalling on Railroads.

MESSRS. G. [illegible], C. & P. Engineer, and S. Woodward, Superintendent of the Cincinnati Southern Railway, under instructions from the president and general manager, have recently investigated the subject of block signalling for railways, with a view to the adoption of the best system for that road. For this purpose they visited Boston, New York and [illegible]. In their report, after describing the block signal tower system employed by the Pennsylvania Railroad quite extensively on its lines, which involves the construction of an expensive tower every three or four miles, and the constant employment of a skilled telegraph operator at each end of the block, they say in reference to the Automatic Electric Signal System:

Several plans have been suggested and tried to avoid the expensive necessity of a man and a building at the end of each block, by connecting electrically the track with the signal post in such way that every train passing the end of a block will move the signals at each end of the block automatically. The signal discs or arms are generally moved by a falling weight mechanically connected with and held in check by the curvature of an electro magnet, the electric current being supplied through a special wire.

This system, although doing good service on several roads, cannot be considered as perfectly reliable, the operation of the signal, depending as it does on the insulation of the wire, which is affected greatly by atmospheric changes.

A great improvement was lately introduced in this system by the Union Electric Signal Company by the substitution of the rails of the track for the wire as conductors of the electric current. The principal advantages gained by this arrangement are:

First—That the large section of the rail offers so little resistance to the electric current, and the electric tension is so much reduced thereby that insulation of the rails is not necessary, and a single battery jar furnishes a reliable current, which is unaffected by the condition of the weather, the only precaution necessary being to connect every consecutive rail by a piece of wire united to the rails, and to guard against defective contacts at the joints.

Second—That the signals are not only reversed to danger by every passing train, but also by the presence of a car on the track at any point within the block, or by a broken rail or an open switch, all of which are frequent causes of accidents undetected by other systems of signalling.

Third—That the effect of any disorder in the apparatus is: always to turn the signals to danger, which is a most desirable feature in automatic signals.

The undersigned witnessed the operation of these signals on the Boston end of the Fitchburg road, where they have been in successful operation for several years. They are highly praised by the officers, and are now being introduced on other parts of the road.

The Pennsylvania Railroad is now introducing these signals on its main line between Altoona and Philadelphia, for the purpose of subdividing their blocks into smaller sections.

The undersigned believe that the band system and the Union Electric Automatic system should both be experimented upon on the Cincinnati Southern Railway before the division of the entire road into blocks.

They recommend that certain designated sections of the road be fitted up with the block tower system, and tunnels No. 24 and 26 with the Union Electric Signal apparatus, and the two systems thus competitively tested. Their estimate of the expense of construction and equipment for the signal towers: twelve stations is $10,530, and for the Union electric signals, 8 stations, $2,680.

The report and recommendation have been approved and the work ordered to be prosecuted without delay.

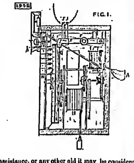
ABSTRACTS OF SPECIFICATIONS.

[*We are indebted to our contemporary The Engineer for the diagrams which illustrate these abstracts*—ED. E.]

1942. IMPROVEMENTS IN AND RELATING TO APPARATUS FOR TRANSMITTING FIRE ALARM AND OTHER SIGNALS.—*By William Phillips Thompson.—(A Communication from Abroad, by Monsieur Jaques Victor Michel Bartelous, of Bruxelles, in the Kingdom of Belgium.)*

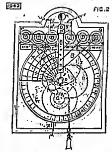
"The automatic system which I have invented," says M. Bartelous, "works by electricity, and enables one to place upon a single wire an indeterminate number of instruments, each possessing a particular signal which makes known to a receiving office which apparatus has been at work." This apparatus can render in particular the following services:—First, it establishes an automatic communication between the notifiers of conflagrations (hereafter called the alarm givers) and an office, whether of police or otherwise; second, it puts into the hands of certain persons a means of prompt communication, enabling them to call in medical or police

1942 FIG. 1.



assistance, or any other aid it may be considered useful to organise, independently of any other applications that the same system may receive. The alarm-givers, whatever be their system, are in electrical communication on the one hand with the ground, and on the other with a terminal, whence the current passes to an electro-magnet. During the passage of the current in the magnet its soft iron cores attract a soft iron armature which terminates transversely a lever. This latter being made of conducting material with the exception of its axis, which insulates it, establishes when in repose electrical communication with the central battery by a movable piece fixed on a shaft. When the lever turns on its axis and takes the new position, this movable piece, which was supported on the lever, is released and takes a new position, the axis turns round a quarter of a circle, and with it the indicator needle K, terminated by a heavy disc which turns and takes the position K¹. This needle moves in a glass case, and according to its horizontal or vertical position one is enabled to see whether the apparatus has been at work or not. The rocking movement of the lever breaks communication with the movable piece, and causes the suppression of the alarm-givers. At the same time the clutch by which the lever is terminated at its other extremity rises and produces the liberation of a wheel, G, which turns round by means of clockwork. On the fore part of the lever F there is a block which, when in repose, rests upon two pieces, themselves supported by rods J, J¹. The right one J¹ establishes communication with the receiving office, the battery, and the earth, the left, J, with the remainder of the system (or line

1942 FIG. 2



wire). The movement of the armature raising the block cuts off all communication with the line wire and receiving office. The interruption of the current from the line wire whilst the apparatus is in action, and its restoration thereto after the revolution of the dies, may be produced by a supplementary mechanism replacing the action of the rods. The first rod is entirely suppressed and replaced by a flexible conducting wire, which connects the terminal J to the cross-piece carried by the lever. The second rod is shortened, and instead of descending to the cross-piece II is terminated at K by a hook at right angles. A metallic piece in the form of a V, and movable round the axis H, replaces the original arrangement. The lower branch of this piece is terminated by a heavy weight, G, which rests upon one of the extremities of the cross-piece I; the other branch ends in a thin blade, and rests when the apparatus is in repose upon the projection K at the end of rod J¹. When in this position the current, therefore, passes from the terminal J¹ through K, G¹, H, G, across the pieces I I, along the flexible wire *f f*, and joins the terminal J, where ends the line wire of the rest of the system. If, on the contrary, the apparatus is at work the lever F, and consequently the cross-piece I I, are raised; the piece G, H, G¹, partakes of this movement, oscillating around the axis H, and the current no longer gets beyond J¹, since the contact is broken between G¹ and K. The wheel G is the medium for giving the signals. It is divided on its first quadrant into six or more concentric bands, each of which is put into communication (by a small wheel rolling upon it as it rotates) with a similar number of contact makers, T, above each of which is inscribed the destination or duty assigned to it. When the apparatus is in repose these little wheels rest upon an insulating band, X Y. In the three other quadrants the wheel does not carry any signals except upon the outside circle, and the signals there inscribed signify, according to their number as to series and order, the house which is setting the apparatus in action. The five concentric bands around the centre carry special arrangements corresponding to the services asked for, and these signals are transmitted by pressing down one of the five buttons T. As to the sixth band it can, by means of a button, L, be put into communication with the office for a voluntary signal of conflagration. It is divided on its circumference into four sections; the first is made of conducting material, divided into a small number of divisions, and sets an alarum in motion; the second, which takes up the rest of the first quadrant, is an insulator; the two last carry signals which indicate the series and number of the house. Whilst the outside circle carries an insulating band, the wheel uses the space to produce special signals. Outside the concentric circles which have just been described there is round the whole circumference of the wheel a metallic band, upon which rests a spring which establishes a permanent communication with the earth. The apparatus is capable of producing two sorts of signals, one sort automatic, the other voluntary. In order the better to explain the working of the apparatus, the wheel is supposed to be divided into sixty divisions, although the system permits of as many divisions and as many contact makers for alarms as experience may show to be useful. As soon as the electric current is closed automatically by the agency of an alarm-giver, an alarm bell rings in the receiving office and gives notice of a conflagration, the armature of the transmitting apparatus turns on its axis, and the wheel G is set in motion. The ringing continues during the rotation of a portion of the wheel, this portion being a conductor, and of greater or less extent, over which I suppose the last concentric circle: during the rotation of the part, since this circle is an insulator, communication is interrupted, and the ringing ceases; but when the three other quadrants of the wheel are passing the successive openings and closings of the current produced by metallic pieces inserted into the mass of the wheel, the greater part of which is insulating, somewhat in the fashion of type in a composing stick, they transmit a series of signals, the particular combination of which indicates first of all the series and then the number in this series of the house whence was despatched the signal of distress.

ment, sont animés d'un mouvement en sens inverse l'un de l'autre; 2° les électro-aimants de chaque mouvement d'horlogerie sont polarisés, l'un positivement, l'autre négativement; 3° il n'y a qu'un seul cadran; 4° enfin, il se trouve entre les deux dernières roues HH de chaque mouvement d'horlogerie (fig. 4) une roue folle, qui est toujours menée par une quelconque des deux roues HH, et dont les dents sont calculées de façon à ce que cette roue O, entraînée par une quelconque de ces deux roues HH, ne soit jamais gênée dans son évolution par l'autre de ces roues HH. Selon que l'un ou l'autre des mouvements d'horlogerie des barillets est actionné par le courant, l'une ou l'autre des deux roues HH fait tourner l'une ou l'autre des deux roues *rr'* dont l'axe commun porte l'aiguille du cadran. L'engrenage de chacune de ces deux dernières roues *rr'* est tel que, menée par la roue à rochet H, elle est sans action sur celle-ci (roue menée non réciproque).

Les déplacements de la roue O sont limités par un régulateur spécial. Cette roue O porte une aiguille appelée à se mouvoir sur un cadran gradué, et qui indique la hauteur de l'eau chaque fois que le mouvement exécuté par le niveau, soit de haut en bas, soit de bas en haut, dépasse dix centimètres. La même roue O transmet ses mouvements à une crémaillère horizontale, qui glisse entre des guides fixes et est munie d'un crayon à molette. Au contact de ce crayon, marche, sur un rouleau moteur parallèle à la crémaillère, une bande de papier animée d'un mouvement uniforme par un appareil d'horlogerie. Le crayon trace ainsi, sans interruption, la courbe exactement figurative du régime des eaux. En cas de crue torrentielle, lorsque l'aiguille arrive au point marqué *danger*, une sonnerie éveille, de jour comme de nuit, l'attention des personnes qui se trouvent dans le voisinage du récepteur; un simple coup d'œil au cadran permet d'apprécier la hauteur des eaux et le degré de gravité du danger. Entre le bord de l'eau et la station, un *seul* fil télégraphique, le fil de ligne L, relie le propulseur au récepteur.

Il est aisé de comprendre les avantages de l'appareil de M. Camille Gros. La science y trouve son compte, car les observations journalières peuvent être automatiquement enregistrées, et on obtient une courbe mathématique du phénomène. Les autres systèmes, et en particulier le téléphone, ne peuvent donner cet important résultat. L'employé est-il occupé, distrait, endormi même, la sonnerie électrique vient l'avertir que le danger accourt, pressant, imminent, et qu'il doit, sans tarder, prévenir l'autorité locale, qui, à son tour, donne l'alarme. Mieux encore : le cadran indicateur peut être placé extérieurement; chacun peut le lire aussi facilement que celui d'un baromètre ou d'une horloge. En comparant ses indications avec les renseignements donnés par un tableau placé à proximité sous cadre grillagé, faisant connaître la rapidité de marche de la masse d'eau en raison de son volume, chaque riverain sait combien d'heures, de minutes, il a devant lui pour mettre sa personne et ses biens en lieu sûr. L'appareil Gros devient alors un véritable instrument météorologique populaire, analogue à ceux que l'on a si utilement placés depuis quelques années dans nos villes pour nous tenir au courant des perturbations atmosphériques, et non moins indispensables que ces derniers.

Après la description de ce télégraphe hydrostatique, faite par M. l'ingénieur des mines Vital devant la Société des lettres, sciences et arts de l'Aveyron, et, sur le vœu unanime de cette Société, le Conseil général de l'Aveyron accorda des fonds pour la construction d'un premier spécimen du système. Des expériences eurent lieu, aux frais de l'État, sur le Lot, entre Penchot et Capdenac, avec une distance de 14 kilomètres entre le propulseur et le récepteur. Elles réussirent complètement, et il est à désirer que l'administration supérieure se prononce d'une manière définitive.

MAURICE GIRARD.

BIBLIOGRAPHIE

Zoologie élémentaire, par FÉLIX PLATEAU, professeur à l'Université de Gand, membre de l'Académie royale des sciences de Belgique. 1 vol. in-18, de la *Bibliothèque belge*. Mons, Hector Manceaux, 1880.

L'auteur de cet ouvrage a adopté un plan original et ingénieux. Après avoir consacré quelques chapitres à des notions préliminaires indispensables, M. Félix Plateau aborde l'étude des différents groupes du règne animal, en choisissant pour chacun d'eux, un type facile à se procurer, et dont la dissection puisse être faite d'une façon pratique par tout le monde. C'est ainsi que la grenouille sert d'exemple pour les Vertébrés, la limace rouge pour les Mollusques, l'écrevisse pour les Arthropodes, etc. Cette méthode excellente est développée avec un véritable talent d'exposition par le savant professeur de l'Université de Gand. La zoologie est avant tout une science d'observation; M. Félix Plateau a voulu l'enseigner par l'observation.

Le Feu à Paris et en Amérique, par le COLONEL PARIS, commandant le régiment des sapeurs-pompiers à Paris, avec 4 cartes représentant les plans de défense de Paris contre les incendies. 1 vol. in-18, Paris, Germer Baillière et Cie, 1881.

Excellent ouvrage, écrit par un auteur éminemment compétent, qui montre ce qu'on fait en Amérique pour combattre l'incendie, et ce qu'on peut faire à Paris avec les ressources actuelles, insuffisantes dans bien des cas. La Ville de Paris ne refusera pas, nous l'espérons, les ressources matérielles les plus complètes, à un corps d'élite, dont le courage, la vaillance et le dévouement sont devenus proverbiaux.

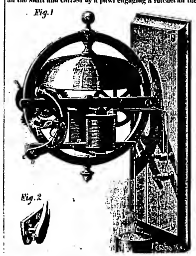
NOVEL STRIKING MECHANISM FOR ELECTRIC BELLS.

The device shown in the engraving provides for a long stroke of the bell hammer, with the movement of the hammer always in one direction. The hammer is made in the form of a segment of a ring, and is carried by a shaft driven by a weight or spring. The hammer is released and stopped by an escapement controlled by an electro-magnet.

The hammer, A, is pivoted loosely to a curved arm placed on the shaft and carried by a pawl engaging a ratchet on the



BOWERS' STRIKING MECHANISM FOR ELECTRIC BELLS.

shaft. The outer end of the hammer is free to swing in and out through a limited distance, but is held normally at the inner limit of its movement by a spring which also holds the pawl into engagement with the ratchet.

On the end of the curved arm there is an escapement pin, *c* (see Fig. 2), and on the armature lever, B, are two lugs, *a b*, placed one for contact with the end of pin, *c*, when the armature is down, and the other for contact with it when the armature is raised in contact with the magnet. The contact of the lugs, *a b*, by pin, *c*, arrests the hammer and prevents its being revolved by the weight.

The curved hammer is below the edge of the bell, at one side, in such position that the hammer strikes at about the end of its upward movement. As the shaft carries the hammer the centrifugal force acting on the long arm overcomes the resistance of the spring acting against the short arm, and throws the end of long arm outward, so as to come in contact with the bell; this checks it and allows the spring on short arm to force the end of long arm inward, when it passes the bell and moves on until arrested by the pin, *c*, and lug, *a*. When the armature is raised by closure of the magnet circuit the lug, *a*, is raised above pin, *c*, and the lower lug, *b*, brought behind the pin. When the armature is released by breaking the circuit the lug, *b*, is carried down, and the pin, *c*, being released, the hammer revolves, and the blow is struck at completion of the revolution.

This invention was recently patented by Mr. George E. Bowers, of Fitchburg, Mass.
